It is not so certain that Sir JOSEPH LISTER would agree that Listerism should be made the justification for neglecting any given detail in the whole realm of hygiene. Rather, indeed, does antiseptic surgery demand that fresh air and ample ventilation and an environment of cleanliness shall be considered as parts of its essence. Nor is the question of sunlight so easily settled in favour of those who advocate retention of the present site and the block plan instead of the pavilion plan. Looking to Professor RAMSAY'S brilliant address at the Sanitary Congress in Glasgow last July the value of sunlight as a health agency is coming to be increasingly recognised. What its comparative amount would be at Piccadilly in Manchester and at the other sites in the suburbs only observation could exactly determine, but the fact is that the best way for Manchester to utilise Professor RAMSAY'S teaching would be, not to carry the infirmary into the suburbs, but to carry the sunlight into the city by removing the pall of smoke which there so frequently conceals the face of the sun. In order, however, to get the full benefit of the sun when it does pierce the smoke, or when the smoke is abolished, Sir DOUGLAS GALTON, who is no mean authority on hospitals, holds that the surrounding open zone should be double the height of the buildings. How this may be in the proposed plans we do not know. As regards administration within the wards there should be little difference between a long ward with two rows of beds and a square ward with four rows, but perhaps in the latter case the wards might be brought within easier reach of the administrative centre. Here, again, reference to the plans would settle the point. The relative advantages and disadvantages of the rival sites will, no doubt, be carefully weighed and measured by the Mancunians, whose business instincts—*pace* the Ship Canal—are not likely to lead them astray. All that we contend for is—and in so far we agree with Dr. HARDIE—that they will do no honour to a principle by turning it into a fetich and

Hosted by Google

that a cast-iron rigidity of adherence to the pavilion system may cost them too much in other important directions.

A MATTER of great interest has recently been agitating the Adelaide medical world. Dr. LEITH NAPIER, the senior resident surgeon of the Adelaide Hospital, brought a charge against Professor WATSON, the consulting surgeon and pathologist, before the board of management of the hospital, in which he accused Professor WATSON of misrepresenting a case that occurred in the hospital. We have received an *ex parte* statement issued by Professor WATSON, but we have the opportunity of checking all his assertions, as we have also received a copy of the official minutes of evidence taken at the inquiry by the hospital board and published by the Government of South Australia. The evidence is most voluminous, but we have extracted the following chief points. The patient, a woman aged fifty years, was admitted into the Adelaide Hospital, having been sent from the Destitute Asylum suffering from a large femoral hernia, with signs of strangulation (vomiting and constipation), of two or three days' duration. About two hours after admission an operation was performed by Dr. SHEPHERD, assisted by Dr. NAPIER. An incision was made over the swelling in the left groin and the sac of the hernia was opened. It was found to contain omentum, but no bowel could be discovered, though both Dr. SHEPHERD and Dr. NAPIER examined the crural canal with the finger. The mass of omentum was ligatured a little below the neck of the hernial sac and removed. Though no bowel was found and no explanation of the symptoms of obstruction of the intestine was discovered, yet the wound was closed and the patient sent back to bed. The two operators state that the woman was too much collapsed for any further operative procedure. The patient died during the night. Thus far no important differences of statement exist. The accounts of what was found post mortem are less in accord, though both sides agree that no bowel was discovered in the hernia and that the great omentum was firmly adherent to the left crural ring. Professor WATSON states that under this omental band was a loop of small intestine about fifteen inches in length, which was so compressed by the pressure of the band that it was congested and its lumen constricted. To this he attributes the symptoms of strangulation from which the patient was suffering. He had previously to the necropsy expected that a knuckle of bowel would be found in the crural ring. Dr. NAPIER declares that no abdominal condition was found at the post-mortem examination which was sufficient to account for death and that no proof of any intestinal obstruction was discoverable. The evidence of Dr. RAMSAY SMITH was to the effect that the omentum formed a "pretty tight band," from under which was pulled a piece of small intestine much congested, but with no adhesions to any structure. Others present noticed the piece of congested bowel, but did not observe its relation to the omental band.

Looking at the matter from a purely surgical point of view, and taking into consideration only the most essential facts, we can come to no other conclusion than that at the time of her admission into the Adelaide Hospital the patient was suffering from an acute intestinal obstruction. That this was the opinion of Dr. SHEPHERD and Dr. NAPIER is shown by the fact that they operated, attributing the symptoms to strangulation in a hernia from which the patient was suffering. At the operation, finding no bowel in the hernial sac, they appear to have thought that the vomiting and constipation were due to the strangulation of the omentum. Now the symptoms produced by a strangulated omental hernia are exceedingly slight until it becomes gangrenous and it never gives rise directly to signs of obstruction. Having found no sufficient cause for the symptoms present two courses were open to the surgeons. Either they might have followed up the omentum to the crural ring itself or they might have performed laparotomy. The second alternative was undoubtedly preferable, if the patient's general condition had admitted it; if laparotomy were inadmissible, as apparently in this case, we think no surgeon would hesitate to follow up the incision already made to try to discover the cause of the obstruction, unless, indeed, the patient were moribund, and this could hardly have been the case in the present instance, as the woman lived seven or eight hours longer.

As to the post-mortem examination, all agree that the omentum was firmly adherent to the crural ring, and so many of those present agree that a congested loop of small intestine was drawn from beneath the omental band that no other decision can be come to than that the omentum had caused intestinal obstruction by constricting this loop of bowel. This explanation clears up all the difficulties of the case, and we cannot refrain from saying that it appears to us to be intrinsically very highly probable. It is by no means very rare to find that an adherent piece of omentum has caused strangulation of a portion of bowel by holding it down; this is one of the recognised dangers of omental herniæ. Some of those who gave evidence seemed to be under the impression that adhesion of a piece of bowel was necessary to cause strangulation. The Board, after hearing the evidence, called upon Professor WATSON to resign, and without any technical knowledge took upon themselves to decide that "the operation was skilfully performed" and "that the post-mortem examination fully justified the treatment."

IN another part of our columns will be found a detailed account of the arrival of the Royal Mail steamer *Nubia* at Plymouth with cases of cholera and suspected cholera on board, and we think that no one reading this account can doubt for one moment the superiority of the present system as compared with the old one of quarantine. In this case the vessel has been retained but for a short time, and had not Imperial troops been involved the detention would have been shorter still. The sick have been separated from the healthy, and, after careful medical inspection, such persons as could conveniently be allowed to land have proceeded to their destinations, there for a time to remain under medical supervision and to be dealt with at once if any suspicious symptoms should arise. The cholera regulations have long since more than justified themselves, and the disease, although within recent years it has penetrated what may be called our first line of defence, has in all

Hosted by Google

cases been rigorously dealt with. In the old days, and in spite of quarantine, both cholera and plague played havoc with our population. All attempts to keep these diseases from us were futile, and on obtaining a footing they spread with an awful rapidity and effect. The present system in no sense professes to keep out every case of cholera from our midst, but it makes provision for dealing with such as arise and for reducing the chances of introduction to such a minimum as is consistent with a due regard to the safety of the persons who may have been shut up in an infected vessel, and with the freedom of passage of the vast mercantile marine of this great empire. In the olden days the travellers on board the *Nubia* would not have reached their homes in this country for many days, perhaps weeks, to come, and it is extremely probable that, had they been left on board shut up with the sick, some would never have seen their homes again. In arriving at Plymouth the *Nubia* reached a port where she could be efficiently dealt with. Mr. WILLIAMS, we are assured on all hands, is a most competent officer, and he has besides, acting under him, an inspector of great experience. In addition to this the port sanitary authorities of Plymouth are an eminently enlightened body, and not only have they supported their medical officer of health, but they have equipped their port with adequate isolation accommodation and with modern disinfecting plant. In this manner not only is the country protected, but, as must come home to every man of Plymouth, the town itself is rendered as secure from invasion as a port doing the large trade which Plymouth does, and situated as she is, can well be. Certainly the Plymouth port sanitary authority have every reason to congratulate themselves upon the provisions they have made. Had they discontinued their preventive measures, Plymouth might at this moment have been pointed at by the nation with scorn, but in so far as the authority is concerned, it, in the matter of the *Nubia*, has done its part well. It is these unexpected visits of cholera-infected vessels which more than justify the Cholera Surveys which were recently undertaken on the initiative of Dr. THORNE THORNE by the Medical Department of the Local Government Board. Instances such as these will show the public the foresight of that department, and the promptitude with which it acts. Let the port sanitary authorities throughout the kingdom mark well what has happened at Plymouth, and let them call upon their medical officers of health for a report setting forth what these officers propose to do with the plant the authorities have provided them with, in the event of their being visited by a ship in a similar condition to that in which the *Nubia* came to port. Let port sanitary authorities, too, remember that cholera may come to them even in January, and let them also take heed lest they find a case of bubonic plague in their midst.

THE SCOTTISH FORM OF OATH.—The West Riding magistrates in the Leeds division have decided to accept the Scottish form of oath. While we are very glad to learn that this bench has thus endorsed our oft-repeated assertions that "kissing the book" is an uncleanly and dangerous habit we wish to point out that the decision of the bench was a work of supererogation. By the law of the land any witness could claim to be so sworn before them, whether they accepted the form or not.

Annotations.

"Ne quid nimis."

THE QUEEN'S COMMEMORATION.

THIS year, we may well hope and trust, will see the completion of the sixtieth year of the reign of Her Most Gracious Majesty. It is natural, therefore, that every loyal subject should wish that a reign of unprecedented length, one so full of welfare to her people and of glory to herself, should be marked by some special and enduring memorial. The Prince of Wales has stated through the public press that he "desires to intimate that Her Majesty still adheres to the decision already announced to refrain from expressing an opinion upon any proposals for doing honour to herself. His Royal Highness is, however, confident that the Queen will readily appreciate any undertaking to celebrate this event which may be the outcome of the wish of the people, whether generally or locally expressed. He feels assured that, on considering the various suggestions, due support will be given to works of mercy among the sick and suffering and to anything which may tend to brighten the lives and ameliorate the condition of Her Majesty's poorer subjects." The matter of the last paragraph covers such a wide field that we may well find it difficult to make a selection with regard to some good work by which to commemorate the occasion. There are, however, two objects which seem to us to have paramount claims. The one, adequate support for hospitals; the other, some provision other than the workhouse for sheltering the deserving poor in the winter of their days. And first, as a medical journal, we must consider the claims of hospitals, and remember that there are at least three important facts connected with the very existence of these institutions. First, it is generally allowed that hospitals do an immense amount of good by relieving pain and suffering, both directly, and indirectly, by training the coming generations of medical men. Secondly, we believe we are right in saying that every metropolitan hospital except St. Bartholomew's is either in debt or has had at some time to close some of its wards owing to loss of income. Thirdly, it will not be denied that the charity administered by hospitals is enormously abused and that those who have no right to such charity come and ask for it in the most unblushing manner; nay, more, that owing to the competition between the various hospitals for the subscriptions of the charitable sufficient care is not exercised in excluding unsuitable cases from a desire, laudable enough in itself, to show a large record of work, and this action not only diverts charity into a wrong channel, but is a chief cause of the ever-increasing load of debt. To free the public hospitals of the metropolis from debt will, it is estimated, require a sum of from £800,000 to £1,000,000, and as difficulties have arisen in the matter of raising such a sum it has been proposed instead to endow the Queen Victoria Jubilee Institute for Nurses. With this proposal we cannot agree; the nurses had their turn in the jubilee year, and it is now the turn of the hospitals. As to raising the sum, there ought to be no difficulty in such a year as this. As to the best way of using the money when collected there may be differences of opinion. The question is a most difficult one, for it is quite likely that, were the hospitals freed from debt, in some years' time they would be just as badly off as they are now, and until the unendowed hospitals are relieved from the dread of losing subscribers if they turn away cases, however unsuitable, there will always be the temptations and environment which dispose towards extravagance and debt. And for our second proposition, we would plead for some means of lightening the declining days of the honest and respectable

Hosted by Google

poor. Even one more foundation like the Charterhouse would be something—we do not mean for the same class as Sutton provided for, but for those who have toiled through life for a small pittance, and who dread, and rightly, the workhouse, with its absolute lack of all connoted by the word "home."

THE MEDICAL STRIKE IN PARIS.

THE strike of the medical officers attached to the night service of the eleventh arrondissement of Paris has caused obvious inconvenience to the poor of that populous quarter. From motives of humanity Dr. Bellanger and Dr. Hereck have consented to continue provisionally their service, but this does not suffice. Thus, last week several persons applied to the police station of the district for medical help. The police, on inquiry, however, found that the two medical men were out and engaged attending to other patients, so they had to send away the applicants and no help could be given. M. Pourest, municipal councillor for the district, has forwarded an energetic protest to the Prefect of Police, urging that the service should at once be re-established, as the proposed alterations were causing grave injury to the poorer inhabitants of the district. According to a report submitted to the Paris Municipal Council by M. Edmond Gibert it appears that this night medical service cost 141,106 francs (£5640) during the year 1895. It is much appreciated by the population of Paris, but it is now maintained that abuses have arisen. Persons who have means to pay for medical advice are stated to have availed themselves of this service. Such abuse, it is true, does not, as in the case of hospital abuse in England, represent a loss to the medical profession, for the medical men are paid eight shillings per visit by the municipality, but it is a loss to the ratepayers. The latter are therefore interested in preventing abuse, whereas if the proposal of the Prefect of Police were enforced there would be no check to the abuse. If the medical officers were paid a fixed salary it would not matter to any one except to the medical men themselves how many patients resorted to the night service or whether these persons were rich or poor. As it is, the payment being per visit, the authorities have every interest to watch and see that none but the poor avail themselves of the medical officers' services. It is proposed that the tax collectors should be employed to investigate the cases. They are best informed as to the financial resources of the inhabitants of their districts, and, in any case, know all those whose rent amounts to £20 and upwards, for there is no direct taxation levied from tenants who pay a rent below £20. The fact that the cost of the service has increased rapidly strengthens the supposition that abuses have arisen. In 1891 the night medical service for all Paris cost 110,000 fr. In 1894 it cost 27,000 fr., and in 1895, as already stated, 141,106 fr. No less than 135 medical men are engaged in this service, and it is calculated that if, instead of being paid 10 fr. a visit, they each received a regular income of 600 fr., this would only cost 81,000 fr.; but to this it would be necessary to add the midwifery fees, and therefore the saving on the figure given for the year 1895 would have been, not 60,000 fr., but 45,000 fr. Thus if the alteration proposed had been applied in 1895 it would have saved £1800 out of a total outlay of £5640. For a large and wealthy town like Paris, with a population of two and a half million, was it worth while disturbing an eminently useful service so as to economise the paltry sum of about £1800? If abuses have arisen these certainly should be prevented, but the alteration proposed will, on the contrary, give every facility for their increase. As it is, we can but repeat that every time a medical man is called up in the night it means eight shillings out of the rates; therefore, there are any number of persons interested in seeing that none but the poor avail themselves of this service. When, however, the medical officers in question are paid a regular salary, irrespectively of the number of patients they may have, what will it matter whether rich people or only poor people profit by their services? Besides, as we pointed out last week, it is manifestly unfair that medical officers who live in poor quarters should not be paid more than those who live in wealthy quarters, where there is little or nothing for them to do. We fear the Prefect of Police has looked upon this question purely and solely from the financial standpoint, without any consideration, or perhaps without any knowledge, of its other and indirect consequences. We trust that when these arguments are submitted to the authorities concerned better and wiser measures will be taken.

UNQUALIFIED ASSISTANTS AND THE ROYAL COLLEGE OF PHYSICIANS IN IRELAND.

THE following resolution has been passed by the Royal College of Physicians in Ireland:—"That the College condemns the employment of unqualified assistants by any of the Licentiates, and instructs their Representative on the General Medical Council to urge on the Council to suppress the practice by every means in their power." The Royal College of Physicians in Ireland has shown a disposition to sympathise with its Licentiates in their contest against modes of practice that discredit the profession. It does so here. But it scarcely does all it can. It has powers of discipline over its own Members and Licentiates, and it should exhaust them before calling on the General Medical Council. Men are scored off the Register year after year that might have been saved from such a fate by the timely discipline of their own Colleges.

HOSPITAL ABUSE.

A CASE was tried in the Queen's Bench Division on Jan. 12th which is of considerable interest to those who are anxious regarding hospital abuse. According to the account in the *Daily Telegraph* of Jan. 13th the complainant, who kept three public-houses, received severe bodily injuries. He was first moved to the house of a medical man close by, and from there was taken in an ambulance, not to his own residence, as might naturally be expected, but to the West London Hospital, where he "underwent an operation." Not only did he receive the benefits of the hospital to this extent, but he subsequently attended as an out-patient for "some time." It is interesting to know that this recipient of the benefits of charity had subsequently to sell his public-houses for the "low price" of £21,000, as the takings fell off to the extent of £7 a week! This case happens to come into court, and accordingly stands painted in its full colours. There is scarcely a hospital in London which is not thus weekly abused and in the aggregate the system of gratuitous attendance upon accidents in all classes of society is amounting in London to something like a public scandal. While everyone, be he peer or pauper, has a right to accept or receive at a hospital first-aid in some accidents it is only right to point out that as soon as such patients can be moved they should pass to the care of their own medical advisers and certainly should not attend as "out-patients." Such cases demonstrate a scandalous mismanagement of charitable funds, which should no longer be tolerated. Our London hospitals are in a state of chronic impecuniosity. How can we approach the rich and ask them to bestow their funds to be utilised in this manner? Even supposing that the patient gives a handsome donation to the funds of the hospital, this does not relieve him of the charge of depriving the medical profession of their just fees. The vast majority of accidents, as fractures and the like, could be perfectly well treated by the family medical attendant in occasional consultation with a hospital

Hosted by Google

surgeon. We commend this practice of gratuitous attendance upon accidents among the "well-to-do" to the serious consideration of the lay governors of our large hospitals, with whom lies the power to do their duty and put an end to a state of things which, as this case sufficiently demonstrates, undoubtedly exists and much weakens the case of the hospitals in appealing to the wealthy for funds.

SIR JOSEPH LISTER'S PEERAGE.

WE are glad to be able to announce that Sir Joseph Lister on being raised to the Peerage has selected the title of Lord Lister. It is eminently satisfactory to find that he will still be associated with the name which he has made famous throughout the scientific world and that his identity will not be obscured under some territorial designation.

HOSPITAL SHIPS.

IT is stated that ships for ambulance purposes are to be added to the navy of the United States. Their uses will be found described in the pages of THE LANCET in an interesting paper entitled "Hospital Ships" by Dr. Murray Braidwood published on April 4th, 1896, and illustrated by plans. It is sincerely to be hoped that our naval authorities will turn their attention to this subject. One or two of these ships are really wanted, and there is no reason why our nation should be behindhand.

MEDICAL PRACTICE IN ZULULAND.

A GENTLEMAN who has recently accepted a Government medical appointment in Zululand has written to us as follows:—"Medical practice in Zululand, like all Gaul, is divided into three parts—that by the district surgeons (of whom there are five), that by the Kaffir doctors, and, of course, that by the ubiquitous quack. The two former have to obtain from the Government a licence to practise, for which each alike pays a guinea a year. The district surgeons get a salary of £200 per annum and extras, with permission to practise if they take out the licence. The practice and extras amount to about £30 a year, as told to me by one of them, who, however, supplements his income by acting as a missionary, and some have £50 a year for conducting a dispensary, at which they must attend all natives at a uniform fee of one shilling. The shilling goes to the Government, which supplies the necessary medicines; the district surgeon, however, is expected to provide surgical instruments. The dispensary system does away with all chance of native practice, which before its institution used to yield a fair income, as the natives cannot see why they should pay more than 1*s.* for private attendance when they can have attendance and medicine at the surgery for that sum. The term 'extras' means a travelling allowance per mile, outside a six-mile radius, of 1*s.* out and 6*d.* return, to obtain which the practitioner has to keep one or two horses and a groom and must frequently sleep at Kaffir stores, where the charges are from 5*s.* to 7*s.* 6*d.* a night for his horse, 2*s.* 6*d.* for his bed, and 2*s.* 6*d.* for each meal. This item is therefore a source of loss rather than of profit. No allowance is made for evidence in courts of justice, for inquests, or for post-mortem examinations. The white population, including the military, numbered until recently about 700. I do not think that at present it exceeds 500, and the military surgeon at Eshowe takes what private practice he can obtain. No houses are provided by Government, and the district surgeon must build a hut, sleep in a tent, or provide a dwelling-place as best he can. This in the case of a bachelor and a young man (and no other should be appointed to these posts) is not of such consequence; but for an elderly man, a married man, or, above all, one with children, it becomes a serious matter, as a whole family must crowd together in one room which answers for all purposes in a manner which would not be tolerated in the East-end of London, and besides there are no educational advantages whatsoever. The collapse of the Nondweni goldfields (at which place there was until recently a resident surgeon) has sent most of the people there away. This was the only place in Zululand which supported a medical man of its own. Since his departure the N'qutu district surgeon easily combines the practice there with his official duties, although the two places are thirteen miles apart. The cost of living in Zululand—principally on account of the very high rate of freight by rail through Natal and by bullock waggon in Zululand, as well as through the mealie famine, the locusts, and the rinderpest in other parts of South Africa—is extremely high, in addition to which the Government salaries are very disproportionate to necessary expenditure and much below what is usually paid by others. Tradesmen even, carpenters, and blacksmiths can get from £28 to £30 a month—horseshoes cost 10*s.* a set. Even young fellows under twenty are drawing salaries of from £15 to £25 a month at the mines, without any trade or profession whatsoever. The quacks seem to go on the even tenor of their way here as elsewhere and do a roaring trade, not only at extracting teeth at 1*s.* each, but at bone-setting, surgery, and the practice of medicine generally, uninterfered with by the Government. Taking one consideration with another the life of a district surgeon in Zululand is, like the policeman's, 'not a happy one.'"

THE PRESIDENCY OF QUEEN'S COLLEGE, CORK.

THE Presidency of Queen's College, Cork, which is now vacant, is said to lie between Sir Rowland Blennerhassett, Professor Corby, and Mr. Starkie. To our mind Professor Corby's claims completely outweigh those of the other two gentlemen. He is a graduate of the College and at present holds an important Professorship therein—that of Midwifery. He is a man of learning and culture outside the profession, and the esteem in which he is held by his colleagues is shown by the fact that he has been four times elected to the council of the College. This intimate connexion with the College is the finest testimonial that a candidate could possess to his fitness for the vacant Presidency; but in addition to it Professor Corby would represent the body of the College in a way that neither of the other claimants could hope to do. Three-quarters of the students at Queen's College, Cork, hope to enter the medical profession, so that it is very fitting that the President should belong to that profession. If the Presidency had been held on many occasions, or for many years, by a medical man we would willingly admit that a layman might for many reasons be an advisable choice. But this is not the case. It is the turn for a medical man, and a medical man would be a grateful selection to an enormous majority of the graduates and students of the College.

A QUACK AND HIS VICTIM.

AS truly as the earth requires its atmosphere, so the knave requires for success in his duplicity the company of ignorant and foolish neighbours. So long as he can find these he will flourish in some degree, and so long must they serve and suffer for him. If at last there comes an awakening one can hardly be blamed who pities neither him nor them. It is with no deep feeling of regret that anyone endowed with ordinary honesty and good sense will regard the fate of one who was thus duped by a heartless impostor in the name of medical service. The case was tried a few days since at the Burnley Quarter Sessions. The plaintiff, a carter, had been induced to part with over £12 to a travelling "specialist" before he discovered, on seeking the advice of two medical practitioners, that he was himself a fairly healthy

Hosted by Google

man, though weak, and that he had been victimised by an unscrupulous quack. The result was no gain to him, though it obtained for his quondam adviser an exchange from the perils of a false position to the security of twelve months' imprisonment. The excuse of ignorance might be pleaded by the sufferer in this case, and there are others like him in every rank of society who should know better, but do not. In their interest we are pleased to find the law as regards fraudulent money-getting so sensibly interpreted. The lesson of experience, which is all in favour of qualified practice, will not, we trust, be missed in this case because it has not been more severely taught.

A GENEROUS GIFT TO THE SOUTH WALES COLLEGE.

GENERAL regret will be felt at the announcement now made that Professor Alfred Hughes will be compelled, owing to the continued ill-health of his wife, to leave the neighbourhood of Cardiff before the end of the winter session and consequently to resign his chair of Anatomy in the University College, Cardiff. Before leaving he has granted to the College the free use of his anatomical collections, on which he has spent large sums of money and many years of labour. In the event of his wishing to remove them at some future period he has placed at the disposal of the College a sum of money sufficient to replace them. Professor Hughes brought with him from Edinburgh the reputation of being one of the most popular and successful of the extra-mural teachers, and during his short tenure of the chair at Cardiff he has added to his former reputation. It is fresh in the minds of many that one of his students obtained only last summer the exhibition and gold medal in anatomy given by the University of London, an honour only twice obtained by a provincial school during the last twenty years.

DERMATITIS CAUSED BY THE ROENTGEN RAYS.

THE *Boston Medical and Surgical Journal* contains several letters on the subject of dermatitis caused by the Roentgen rays. Dr. J. C. White mentions a case occurring in the Massachusetts General Hospital where a young lady was exposed to the rays for half an hour in one day and for forty-five minutes on the next day, the tube being placed about six inches in front of her sternum. On the following day the skin over this region was red; it subsequently became blistered, and three months afterwards there was an area of angry-looking granulations. Dr. E. A. Codman of Boston attributes these effects to the brush discharge from the vacuum tube or possibly to the ultra-violet rays. Professor Elihu Thomson, writing from Lynn, Massachusetts, describes his personal experience. Desiring to test the action of the rays on the skin, he held his left little finger close to a vacuum tube for half an hour, about one and a quarter inches from the platinum source of the rays. For about nine days very little effect was noticed, then the finger became hyper-sensitive to the touch, dark red, somewhat swollen, stiff, and soon afterwards it began to blister. The blistering started at the maximum point of action of the rays and spread in all directions, covering the area exposed. The letter giving these particulars was written by Professor Thomson on the day three weeks after experimenting with his finger, and the blister then covered the whole exposed portion of its back and sides. He estimated that the equivalent exposure at six inches distance would be about ten or twelve hours. He was not prepared to admit that the brush discharges had anything to do with causing the injury, because the potential was low, being obtained from a small 24-plate static machine and there were no perceptible sparks from the tube to the finger. Professor Thomson mentions a case in which a young man engaged in testing Crookes's tubes at an electrical works had to discontinue the employment because his arms began to be affected, even through his clothing; he adds that two similar cases, but of far greater severity, occurred in Mr. Edison's laboratory.

NEW VACCINATION ORDER BY THE LOCAL GOVERNMENT BOARD.

THE Local Government Board has issued a general order dated Jan. 7th, 1897, amending paragraphs 5 and 6 of the "Instructions for vaccinators under contract" contained in the order dated Feb. 28th, 1887. The new order directs that those paragraphs as at present existing shall be replaced by the following:—

"5. Endeavour to maintain in your district such a succession of cases as will enable you to vaccinate with liquid lymph directly from arm to arm at each of your contract attendances. When stored lymph, whether humanised lymph or calf lymph, is used, it should be preserved either dry on ivory points, thickly charged and constantly well protected from damp, or liquid in tubes, hermetically sealed at both extremities. With all stored lymph caution is necessary lest in time it have become inert or otherwise unfit for use.

"6. Consider yourself strictly responsible for the quality of whatever lymph you use or furnish for vaccination. In storing lymph be careful to keep separate the charges obtained from different subjects and to affix to each set of charges the name or number in your register of the subject from whom the lymph was derived. Keep such note of all supplies of lymph, whether humanised lymph or calf lymph, which you use or furnish as will always enable you to identify the origin of the lymph. Do not employ lymph supplied by any person who does not keep exact record of its source."

THE INDIAN FAMINE.

THERE can no longer be any doubt as to the reality of the famine in India and of the great gravity of the situation. Funds are urgently needed to meet the calamity and cope with the distress and suffering entailed upon the natives of India, especially the unhappy women and children of that country. The crisis is a national one, and we make no doubt that the people of this country will respond to the call upon their pity and benevolence in a generous spirit and in the way they have always done when once they have realised the need. To those who have no actual personal experience of India it is difficult to form any adequate picture of the extent and poverty of its population. As we have already said, the struggle for subsistence with the "masses" is a very hard one at the best of times; but in times like the present it is an impossible one; they patiently succumb and die. To the Government of India falls the responsibility of ascertaining, in the first place, the probable extent of any threatened calamity and of organising the necessary machinery for its relief. That has now been done, and it remains for all classes in this country to do their best to aid the Government in their good work—viz., of mitigating at any rate, if they cannot altogether avert, the sufferings of their Indian fellow-subjects.

THE RED CROSS SOCIETY IN RHODESIA.

WE have received the report of the British National Society for Aid to the Sick and Wounded in War, better known as the British Red Cross Society, with regard to its work during the operations in Rhodesia during 1896. The report opens with a *résumé* of the work of the society since 1886 when the last report was published. From this we learn that the society has made grants to various bodies for purposes germane to its work, among which we may note a grant to the fund initiated by the German Red Cross Society to assist M. Henri Dunant, and a special grant to the Italian Red Cross Society for work in Erythræa. On April 21st, 1896, it was decided to dispatch two surgeons to Rhodesia, and the gentlemen selected were

Hosted by Google

Mr. W. G. Sutcliffe, F.R.C.S. Eng., L.R.C.P. Lond., and Mr. W. Redpath, M.R.C.S. Eng., L.R.C.P. Lond., who arrived at Bulawayo upon June 4th, having experienced considerable difficulty in the matter of transport on the way. Both surgeons saw a good deal of rough work, being several times under fire, and from sundry letters published in the report their services appear to have been warmly appreciated by the authorities, both civil and military. Mr. Sutcliffe has an interesting little note about the comparative effects of the Martini, Snider, and Lee-Metford bullets. The two first do the most damage to the tissues. "The few Lee-Metford wounds that have come under my charge have done very little actual damage. In one case a man was shot nearly a week ago through the right lung, the bullet coming out behind through the scapula, and making a perfectly clean cut which has completely healed, and the man will soon be fit for work again." It should be noted with approval that the names of these gentlemen have been placed on the Medal Roll of the Medical Staff Corps in view of the possibility of a medal being granted to those who have served in the campaign.

IMMATURE INFANTS IN FRANCE.

THAT the threatening depopulation of France is a most serious misfortune against which our neighbours are striving in a variety of ways and with greater or less success, cannot, unfortunately, be gainsaid, but even in this lamentable case the old proverb, "'Tis an ill wind that blows nobody good," may be applied with perfect accuracy. A persistently diminishing birth-rate might well be looked upon as an evil out of which no benefit could possibly arise, and yet with respect to one fragile, but by no means unimportant, section of the French community the national unfruitfulness has proved itself to be a veritable blessing in disguise. The heretofore forlorn beings who have thus fortuitously derived benefit from the general calamity are the newly born infants, who from various causes, but chiefly by reason of their premature appearance on the scene, are peculiarly unfitted to withstand

> "the thousand natural shocks
> That flesh is heir to."

Formerly no very serious efforts were made to prolong the ephemeral existence of these unwelcome little strangers. They were rather hopelessly allowed to pine away and die, under the impression that they could not possibly survive, but human life has of late become so valuable in France that no breathing waif need now be abandoned as an irretrievable derelict. Little children have ever been esteemed the most precious of human possessions all the world over, but it was reserved for an energetic Frenchman to set the seal upon this preciousness by conserving the immature specimens in glass cases. That this is simply a statement of fact many of our readers are doubtless already aware, but should there be any questioners among them they have merely to pay a visit to No. 26, Boulevard Poissonière, Paris, in order to obtain resolution of their doubts by ocular demonstration. At that address, under the designation "Œuvre Maternelle des Couveuses d'Enfants," they will find a truly remarkable institution, which owes its inception and development to the zeal and philanthropy of Dr. Alexandre Lion of Nice. Ruminating one day on the perilous condition of his country from a demographic point of view, it struck this patriotic and humane member of the medical profession that the holocaust among prematurely born infants would be largely diminished if the helpless atoms could only be kept sufficiently warm. Accordingly, in 1891 he invented his *couveuse*, or modified incubator, which may briefly be described as a woven wire mattress suspended in a glass case, the latter being heated by a water coil and kept sweet and wholesome by a constant inflow of purified filtered air. The success attending on this new departure in infant life preservation has been surprising. A prematurely born child, if exempt from hereditary disease, never dies in Dr. Lion's institute provided it weighs not less than two and a quarter pounds — that is, about one-third of the normal standard—and provided, also, that its installation in the *couveuse* is accomplished with the least possible delay and exposure. At this stage of the untimely bud's frail existence a chill is almost certainly fatal, so the transfer from the lying-in bed cannot take place too soon or be carried out too carefully. The theory that immature infants require exceptional warmth is, of course, not a new one. Every midwife knows the importance in such cases of immediate swaddling; and children born before their time, whose survival was regarded as well-nigh hopeless, have ere now been saved by such devices as enwrapment in newly-flayed skins, the utilisation as cradles of freshly eviscerated sheep and goats, &c. The inventor of the *couveuse*, nevertheless, amply deserves the lion's share of the credit, not merely on account of his ingenious amplification of a well-known principle, but also for his untiring advocacy and capable organisation.

THE IRRUPTION OF TEETH INTO THE NOSE.

IN the *New York Medical Journal* for Dec. 26th Dr. Alexander McCoy publishes a series of cases illustrating the irruption of the teeth into the nasal cavities. This painful and fortunately rare condition, he observes, is attributable, as a rule, either to abnormal development with rotation of the dental germ—the enamel growing upward instead of downward—or to extra-follicular development. A case originating in traumatic displacement of the normally irrupted tooth is also recorded. As a rule, the floor of the nasal passage is the seat of the invasion the enameled crown presenting, though extra-follicular irruption at a higher point is also recorded. As might be expected, the offender is usually a front tooth, incisor or canine, but others as far back as the wisdom teeth have been found thus displaced. The clinical interest attaching to cases of this kind is largely that of secondary disturbances which comprise local necrosis, with suppuration consequent on the boring action of a hard body travelling through previously-formed bone, otitis, and even laryngeal spasm. The journey performed by such erratic teeth is sometimes neither short nor rapid. In one case, as read by the light of symptoms, a wisdom tooth appears to have made its way during a period of thirty years through the alveolus into the antrum of Highmore and thence by ulcerative inflammation through the lateral nasal wall and inferior turbinated bone on to the nasal floor, whence it was ejected.

IN the Court of Appeal, on Jan. 13th, the application for a new trial in the case of Beatty *v.* Cullingworth was heard before the Master of the Rolls, Lord Justice Lopes, and Lord Justice Chitty. Their lordships dismissed the appeal without calling on counsel for the defendant.

THE Russian Academy of Science has elected Lord Kelvin an honorary member and Lord Rayleigh and Professor Bury of Dublin University corresponding members. Dr. Simon Newcomb of Washington, the American astronomer, was also elected an honorary member.

THE death, on the 12th inst., is announced of Deputy Inspector-General (Bengal Army) F. J. Mouat, M.D. Edin., F.R.C.S. Eng. The deceased was formerly also Inspector-General of Prisons, Bengal, and a Local Government Board Inspector.

THE Colonial Office announce that sufficient applications have now been received from candidates for vacant appointments at Lagos and on the Gold Coast.

THE CHOLERA-INFECTED VESSEL AT PLYMOUTH.

THE arrival of the R.M.S. *Nubia* (Captain Browne, R.N.R.) at Plymouth with cases of cholera on broad was an event hardly anticipated at this period of the year; but, nevertheless, neither the officers of the port sanitary authority nor the Customs were caught hibernating. The *Nubia*, a vessel belonging to the Peninsular and Oriental Company, left Calcutta for London on Dec. 10th, 1896, with her crew and a small number of saloon passengers. On arriving at Colombo on Dec. 17th the vessel took on board some 250 non-commissioned officers and men, as also officers and their wives, and a few soldiers' wives and children. On Jan. 1st the *Nubia* reached Malta, and on the evening of this day the first case of cholera, which ended fatally in twenty-four hours, occurred. Between this date and the 3rd some three other cases of cholera and three or four suspicious cases came to light. Two of the three cholera cases died, one on Jan. 6th and the other on Jan. 9th. On Jan. 8th another case of cholera occurred, and this case also terminated fatally on the morning of Jan. 10th. As to the origin of the outbreak there would seem to be some doubt, for while, on the one hand, cholera is reported to have been prevalent in the native quarters of Colombo at the time the *Nubia* left, no definite case of cholera was recognised until after the arrival of the ship at Malta on Jan. 1st. It is thought, therefore, by some that the disease was contracted from the consumption of fruit purchased independently by the troops at Port Said, but there would appear from the evidence procurable some difficulty in accepting this view, and, moreover, the authorities strenuously deny the existence of cholera in the latter port. As to this, however, it has to be remembered that anomalous forms of cholera may doubtless exist without recognition.

We believe that another view of the outbreak attributes it to the presence of some infected articles taken on board at Colombo, but which may not have been unpacked until after the colder latitudes were reached. There is no question as to the fact that the cases regarded as cholera were typical of that disease. It has, too, to be remarked that before the cases of cholera occurred on board there were several cases of typical dysentery among the Lascars, and that a death, also of a Lascar, took place in the Red Sea from acute diarrhœa. The Lascars, however, occupied a separate part of the ship, and no cases of actual cholera occurred amongst them, such attacks being confined to the unmarried men amongst the troops. With, therefore, the obviously uncertain factors involved it is quite impossible, with a due regard to the elementary laws of logic, to speak definitely as to the means by which the disease was conveyed to the troops. On arrival of the *Nubia* at Plymouth on the 9th with her cholera flag flying she was detained by the Customs, and Mr. Williams, the energetic port medical officer of health of Plymouth, being immediately apprised of the fact, forthwith visited the vessel. It was found that there was then a body dead from cholera on board and also the other cases above referred to. Mr. Williams found that all precautions, as far as possible, had been taken, and that Surgeon-Captain Hardy, medically in charge of the troops, and Mr. Edwards, the ship's surgeon, had done their very utmost under the trying circumstances in which they were placed. Under the provisions of the cholera regulations all hands were mustered and carefully inspected by Mr. Williams, and as a result of this inspection certain of the saloon passengers were allowed to proceed to their destination after they had satisfied Mr. Williams of their condition and of their names and addresses. The vessel was then ordered to steam far beyond the Eddystone to bury her dead; and the captain, while still away from the Sound, was instructed to thoroughly cleanse the bilges of the vessel. Shortly after the return of the *Nubia* from this sad ceremony another patient died, and within a few hours the body was conveyed to sea in a similar manner for interment. On the first arrival of the vessel at Plymouth Mr. Williams telegraphed to the Central Health Authority at Whitehall, and we understand that, such was the promptitude of the Local Government Board, within a few hours Dr. Bulstrode, one of the medical inspectors, was in conference with Mr. Williams at Plymouth. On Sunday morning the *Nubia* was visited by Dr. Bulstrode and Mr. Williams, and these two gentlemen together made a thorough inspection of the vessel and inquired carefully into the history of all the cases. It was then resolved that the remaining cholera patient and the suspicious cases—the former on the previous day having been too ill to be moved—should be transferred from the *Nubia* to the hospital ship *Pique*, which has been so admirably fitted up by the port sanitary authority of Plymouth. This having been safely accomplished, the hospital and other places in which the sick had been isolated were thoroughly disinfected. On Monday morning it was discovered that two fresh cases of suspicious diarrhœa had occurred and these were at once sent to the *Pique*. A communication was then received from the War Office to the effect that they wished to remove the troops to a fort on shore, there to observe them, and to carry out the military details connected with the discharge of the time-expired men. A conference was therefore held between the representatives of the Local Government Board and the port sanitary authority on the one hand, and of the Army, and Army Medical Department on the other, when it was decided that the War Office should take charge of all the unmarried men of the troops (the vast majority) and that the port sanitary authorities should deal with married people and children under the provisions of the cholera regulations. These preliminaries having been arranged the *Nubia* was visited early on Tuesday morning by Mr. Williams, who was accompanied by Dr. Bulstrode. All the troops were paraded on deck and inspected very thoroughly by Mr. Williams, each man being individually interrogated. It is satisfactory to learn that, in so far as cholera symptoms were concerned, all the men were found to be in good health, and, the inspection over, the troops were landed by the Government tug *Scotia* at a spot convenient for access to the fort which had been prepared for them. All the clothing and baggage will be dealt with by the port sanitary authority of Plymouth, who are to be most warmly congratulated on the possession of adequate means for the purpose of submitting the clothing to super-heated steam. After the departure of the troops Mr. Williams mustered the crew on deck and was able to pass them all as healthy. He then gave directions as to the further disinfection and cleaning of the ship, and the *Nubia* shortly after left for Gravesend, where she has now arrived. Several of the passengers who had been dealt with under the cholera regulations left Plymouth by train the same evening. The military authorities, who have been represented at Plymouth by Colonel Elmes, A.A.G., and by Surgeon-Major-General Hamilton, principal medical officer, have, we are informed, acted in complete accord with the port sanitary authority, and where mutual assistance has been possible it has been most cheerfully rendered. The highest praise is due to the officers of the *Nubia*, who have done all in their power to facilitate the precautionary measures.

THE REPORT OF THE ROYAL COMMISSION ON VACCINATION.

AT the meeting of the Society of the Medical Officers of Health, to be held to-day (Friday), Dr. F. T. Bond will submit for the consideration of the society, in connexion with his paper on "How shall we legalise the recommendations of the Royal Commission on Vaccination?" the following propositions:—

1. That the report of the large majority of the Commissioners conclusively shows that in their opinion it is in the interest of the community that the State should continue to promote vaccination, and that it is not expedient that the vaccination of children should be left to the uncontrolled option of parents or guardians.

2. That the report does not contest the absolute and indefeasible right of the State, as the supreme guardian of all children, to enforce their vaccination, but only maintains that it is not expedient, in the interest of vaccination itself, for the avoidance of scandal as well as for the discouragement of mischievous agitation, that the vaccination of children should be enforced in the way now provided for by law.

3. That in the opinion of this society it is expedient that any concession which may be made to what is admitted

Hosted by Google

by the Commissioners to be an exaggeration of dangers which are really "insignificant" and which they believe would be largely, if not entirely, removed by the improvements in the practice of vaccination which they recommend, should not be of the nature of a permanent abrogation of the right of the State to enforce the vaccination of the child, as the Commissioners practically suggest, but only of a postponement of the operation until such time as may be considered suitable for reviving the right of the State to enforce it.

4. That the time for revival of such right is to be found when the child is required to attend school, and that it is expedient, therefore, in any amendment of the vaccination law to make explicit provision for such revival.

5. That it should be the duty of the Registrar of Births, in the case of the registration of the birth of every child, to deliver to the person registering the birth a notice of the requirements of the law in regard to vaccination, together with a suitable explanation of the grounds on which the State requires that the child should be vaccinated, and that he should also inform the public vaccinator of the child's birth.

6. That it should be the duty of the public vaccinator at some time, not less than six and not more than twelve months after the birth of the child, to visit it at its registered home, and if he shall find that the child is alive, and that it has not been effectually vaccinated, and that the operation may with safety be performed, to offer so to do; and that if the person in whose legal charge the child shall then be shall refuse to allow it to be vaccinated, or if for any other reason the public vaccinator should think it desirable that the vaccination of the child should be postponed, he should forward a certificate to that effect to the official who may be appointed to receive and record it.

7. That on the receipt of the certificate of the public vaccinator that the legal guardian of a child who had arrived at the age and was fit to be vaccinated had refused to allow the child to be vaccinated, it should be the duty of the officer to be appointed for the purpose to summon such guardian before the magistrates, and that on such guardian satisfying the magistrates that he objected to the vaccination of the child they should be empowered to make an order suspending the compulsory vaccination of the child until further notice, on payment by the guardian of the court costs incurred in the proceedings.

8. That it should be the duty of the public vaccinator to periodically visit all schools for the purpose of inquiring into the state of the children attending them in regard to vaccination and of effectually vaccinating and re-vaccinating such children as he may find in an unprotected or imperfectly protected condition.

9. That the recognition of the propriety of enforcing vaccination during the school period which would be thus established would materially facilitate the promotion of re-vaccination during the same period, at the time when in public elementary schools the child would be leaving, and that it would thus offer a guarantee for the general protection of the whole population which would not be otherwise obtainable.

10. That the delay in enforcing vaccination which would be entailed on such children as might be thus temporarily exempted would not involve any serious risk either to themselves or to the community as a whole, except in presence of an epidemic, when, as the Commissioners advise, vaccination should be compulsory, whilst, on the other hand, it would carry with it great compensatory advantages, amongst which may be especially mentioned that of relieving vaccination itself of most if not all of the risks and objections to which it would still be exposed even by the extension of the period of liability to six months, as the Commissioners propose.

11. That it is desirable that the certificate of successful vaccination and re-vaccination, whether given by the public vaccinator or by a private medical practitioner, should embody a statement of the number and aggregate area of the scars left after the vaccination punctures have healed, and that it should also carry on its face information as to the minimum conditions in regard thereto which can be reckoned on to afford effectual protection.

12. That it is expedient that the present requirements in regard to the re-vaccination of persons employed in the public services should be maintained, and that employers of labour should, if not required, be at least encouraged to promote the re-vaccination of those whom they employ.

13. That it is desirable in any legislation for the amendment of the vaccination law that the general administration of the medical and sanitary provisions of the law should be delegated to sanitary authorities, due regard being had in so doing to ensuring that the work shall be efficiently done, and subject always to the control of a system of proper inspection.

14. That the necessity for reorganising the machinery of vaccination, which legislation in the foregoing directions would involve, offers a convenient opportunity for dealing with the whole subject of the executive of the sanitary and medical public services, so far as regards the duties of medical officers of health, of district medical officers, and of public vaccinators, and also of meeting the recognised need of providing for the medical and sanitary supervision of public elementary schools; that by a proper consolidation and co-ordination of these now unrelated branches of public work both efficiency and economy might be materially promoted.

15. That it is desirable that the Society of Medical Officers of Health should endorse generally the expediency of giving effect to the following proposals of the Royal Commissioners—viz.: (1) to allow public vaccinators to offer calf lymph as a substitute for human lymph in all cases in which it may be preferred; (2) to extend the period within which a child is at present required to be vaccinated; (3) to provide for the medical treatment of children after vaccination so far as may be necessary to ensure good results; (4) to provide for the more effectual supervision of tramps and common lodging-houses; and (5) to ensure better means than now exist for enforcing the provision of proper accommodation in every sanitary district for the isolation of small-pox and other infectious diseases.

THE PLAGUE IN INDIA.

WE regret that we are unable to report any abatement in the epidemic of bubonic plague in Bombay. Whatever might have been accomplished by the prompt adoption and enforcement of a system of segregation during the earlier and initial stages of the outbreak has passed away; the disease seems to have established a firm foothold in Bombay and the enormous exodus of a panic-stricken population has probably ere this carried the disease-cause in many of the directions whither these people have migrated. The latest reports from Karachi show a rapid increase of the plague there and in a virulent form. Out of a total of 220 cases at Karachi there were 214 deaths, and of 52 fresh cases which occurred in two days all proved fatal. The public health of Bombay, apart from the plague, seems to be in a very unsatisfactory state. The number of deaths registered during the week ending Dec. 24th, 1896, was 1416, being 106 more than in the preceding week, and 946 more than in the corresponding period in the preceding five years. The rate of mortality per 1000 of the population was 87·76. Among the deaths 226 arose from bubonic fever and 352 from remittent fever; and the telegraphic intelligence since received shows, as we have said, a large increase instead of any decrease in these heavy death-ratios. It is very probable, too, that owing to the fears and apprehension of the natives regarding any official interference on the one hand and the desire on the part of the officials themselves not to increase alarm on the other, these figures may not represent the whole truth. The state of affairs in the Presidency of Bombay has not only given rise to much alarm in India, but has very naturally aroused much anxious consideration on the part of the Governments of other countries—such as Russia, Turkey, Egypt, France, and Austria, for example. Surgeon-Major-General Cleghorn, the Director-General of the Indian Medical Service, has been ordered by the Indian Government to proceed to Bombay to report on the epidemic there and on the sanitary condition of the city, and to advise the Government generally. Rogers Pasha, the head of the sanitary department in Egypt, and Dr. Bittar, the bacteriologist of the Egyptian Government, have likewise proceeded to Bombay with the view of advising as to the best measures to be adopted for safeguarding Egypt, especially in the direction of the Mecca pilgrims as possible vehicles for carrying the plague infection to that country and to Europe, of which in this respect Egypt may be regarded as a protecting outpost.

Hosted by Google

Russia, speaking through a portion of her press, apparently advocates the adoption of some joint international sanitary measures for preventing the spread of the disease to other countries; and the Austrian delegate to the International Sanitary Council at Constantinople (Dr. Hagel) proposed to prohibit this year's pilgrimage from India to Mecca in view of the present prevalence of plague in India, and the remaining members of the council agreed with Dr. Hagel; but the Turkish delegate was opposed to the suggestion because to prohibit the pilgrimage would trench upon an essential part of the Mussulman faith. From a Paris paper we learn that Dr. Netter and Dr. Brouardel regard the outbreak in India as a calamity which is bound to engage the attention of Europe, although these authorities believed that owing to the rigorous measures adopted at the various ports, the European continent would be preserved from contagion. Dr. Brouardel urged that England should discourage the Indian pilgrimage to Mecca and exercise the same strict surveillance over ships in the Gulf of Persia as was done in the case of the Suez Canal. The Government of this country is often called upon to play a part on the international stage that falls to the lot of no other Power, and a most difficult part it is—namely, to practically reconcile very grave questions of State policy with those of international sanitary considerations and public health hygiene.

MEETING OF INFIRMARY TRUSTEES AT MANCHESTER.

A SPECIAL general meeting of the trustees of the Manchester Royal Infirmary was held on Jan. 11th to receive the formal statement of the result of the poll in December last Lord Derby presiding. It may be remembered that of 1349 voting papers issued 853 were returned, one of which was bad, and that of the 852 votes recorded 449 were in favour of, while 403 were given against, re-building. The chairman formally announced the result, a majority of 46 in favour of the resolution of the Board. This was the whole of the business, but many questions were asked and a good deal of discussion took place, the chairman saying that though the meeting was practically dissolved and the business concluded "he had endeavoured to give such satisfaction as he could to gentlemen who had asked questions." An informal meeting was then held, Lord Derby again presiding, on the suggestion of the Lord Mayor. After much discussion it was proposed by Sir John Harwood, who said the city council had done all they could to be conciliatory and "had shown the most friendly spirit in relation to the board and to the trustees," that a committee be appointed in equal numbers from the board and the corporation, and he thought that an agreement might be come to which would be "satisfactory all round." Sir Forbes Adam assured Sir John Harwood that it was the wish of the board, acting for the trust, to meet the city council in the most friendly spirit possible. He suggested that the committee should consist of six members of the city council and six of the infirmary board. Mr. J. W. Maclure, M.P., stated that "there was a time when Sir Joseph Heron (the late town clerk) and the corporation prevented the sale of the site to the Government for Post-office purposes." Lord Derby doubted whether as a matter of form the resolution would carry any weight, the meeting being informal, and suggested that "as they had had very valuable expressions of opinion in favour of it they should accept the assurance of the board of the infirmary on the one side and of the city council on the other, that bodies of gentlemen would be appointed in equal numbers to meet and discuss the subject." And so for the present the matter rests.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF FELLOWS.

A HALF-YEARLY meeting of the Fellows of the College was held on Jan. 7th. Mr. N. C. MACNAMARA, the Senior Vice-President, was in the chair in the absence of the President. At four o'clock, when the meeting should have commenced, it was found that there were not thirty Fellows in the room, and it was not until nearly ten minutes later that the Secretary announced that a quorum was present.

The CHAIRMAN moved a resolution to the effect that, "At this meeting of Fellows of the Royal College of Surgeons held on Jan. 7th, 1897, the Council be requested to forward a letter on behalf of the Fellows to Sir Joseph Lister, congratulating him on his elevation to the Peerage." Sir Joseph Lister was the first member of the profession who had been raised to the Peerage for purely professional reasons. Whatever their views as to his work, he was sure that he expressed the opinion of all the Fellows when he said that they hoped that Sir Joseph Lister would be spared for many years to watch the development of the system which he had taught and which had done so much for humanity at large. He considered that such a letter of congratulation would come much better from the Fellows than merely from the Council.

Mr. LANGTON seconded, and the resolution was carried unanimously.

The CHAIRMAN then reported that the resolution carried at the last meeting of Fellows had been reported to the Council on July 9th, 1896, and that in reference thereto the Council had adopted the following resolution, viz.:—

"That Mr. Bryant be requested to forward in the General Medical Council in every way which seems feasible the objects of the Civil Rights Defence Committee in the case of Mr. R. B. Anderson."

Mr. TIMOTHY HOLMES moved the resolution standing in his name:—

"That this meeting desires to call the attention of the Council to the published reports of the proceedings of the General Medical Council in the case of Mr. R. B. Anderson, and to the remarks and action of Mr. Bryant on the occasion, and to ask the Council whether their representative has in this instance correctly construed their instructions."

He said that he moved the resolution as a member of the Civil Rights Defence Committee, and that he wished to disclaim all idea of finding fault with Mr. Bryant's proceedings in this matter, but he had to think of the prospects of Mr. Anderson in the future. If Mr. Bryant were correctly reported in the journals Mr. Anderson would find additional difficulty in obtaining justice. At a meeting of the General Medical Council Dr. Glover moved a resolution that the Council should memorialise the Government on the case of Mr. Anderson; this resolution was opposed by Mr. Bryant. Now, Mr. Holmes continued, it was not Mr. Bryant's opposition to the resolution that was criticised, as even if it had been passed very little good would have been done, but when speaking in opposition to the resolution Mr. Bryant had made several remarkable statements. He was reported to have said that though there could be no doubt that Mr. Anderson had been badly treated, yet there could be no further action in the courts, as the law would not allow it. And yet at the very time this was said an action was impending in the House of Lords. Again, Mr. Bryant had said that it was not within the scope of the College or the Council to help on the interests of an individual in such a way as to make themselves partisans against the law of the country. Surely the Council could not have instructed Mr. Bryant to this effect. Mr. Bryant had further said "that he hoped that Mr. Anderson would be satisfied with a vote of sympathy on the part of the Council and that the Council would not address the Government on any subject unless their cause was strong and they felt it was a question of principle." Surely the very point of the whole matter was that it was a question of principle. He felt that Mr. Bryant had not acted on the instructions of the Council, for what he had said was calculated rather to harm Mr. Anderson's cause than to further it.

Mr. MANSELL MOULLIN, in seconding the resolution, said that many of the Fellows had hoped that the representative of the College on the Council would assist Mr. Anderson before the General Medical Council. Mr. Bryant had not done so, but he had said that there were some weak points in Mr. Anderson's case, though he did not say what they were.

The CHAIRMAN wished to point out that a great deal had been said about Mr. Bryant's "instructions," but the Council had never given any instructions. The resolution of the Council had "requested Mr. Bryant to forward in every way which seemed feasible the objects of the Civil Rights Defence Committee." It was quite within Mr. Bryant's province to say all he had been reported to have said; he was perfectly free to express his own opinions.

Mr. R. B. ANDERSON asked permission to say a few words. He quite agreed with what the Chairman had said about

Hosted by Google

Mr. Bryant's action, and, indeed, he was not sure that even if Dr. Glover's resolution had been carried his cause would have been advanced at all. The cause of the resolution which had now been brought forward was the sweeping character of Mr. Bryant's remarks on the general bearings of the case. Especially had Mr. Bryant declared that the question was not one of principle and that his supporters were acting in opposition to the laws of the country. It was most unfortunate that Mr. Bryant had said this, for his remarks were of more importance than those of the highest judges. He hoped Mr. Bryant would explain his action. He looked to the Council for support in his proceedings to obtain justice.

The resolution was put to the meeting, and as 9 voted in its favour and 10 against it, it was lost.

Mr. WALTER RIVINGTON then moved:—

"That this meeting submits to the Council that no objection can apply to an advance from the funds of the College to prosecute Mr. Anderson's appeal to the Privy Council, and therefore trusts that the Council will sanction a grant for that purpose."

He commenced by pointing out that these meetings of Fellows were instituted for the purpose of bringing the Fellows and the Council into closer relations with each other, and that the Fellows might be consulted by the Council in cases of doubt and difficulty. Mr. Anderson's case involved much difficulty and also some doubt, and as he himself was on the Civil Rights Defence Committee as one of the representatives of the College he had felt that he ought to consult his brother Fellows on the subject. The obligations of the College arose under By-law XV., by which the Council promised to support a Member or a Fellow if his privileges as such were interfered with. Doubts had been felt as to the interpretation of the by-law, but surely it must refer to the external relations of the Fellow, as it could not refer to rights as to lectures at the College, for the only body which could interfere with these rights was the Council itself. The right referred to was the right to practise surgery, and this right existed before the Act of 1858, which merely registered the names of those who were otherwise entitled to practise. The exemptions referred to by the by-law were from serving on a jury or in the militia. Mr. Anderson had certainly been disturbed in the enjoyment of his right to practise.

Mr. CHRISTOPHER HEATH interrupted with the remark that Mr. Rivington had not yet commenced to speak on the subject of the resolution.

The CHAIRMAN ruled that Mr. Rivington was in order, but requested him to come to the special matter of the resolution as soon as possible.

Mr. RIVINGTON, continuing, said that there were three points that he wished to emphasise: (1) that Mr. Anderson had been disturbed in the exercise of his right to practise; (2) that the Council was bound to defend him under By-law XV.; and (3) that the only way in which the Council could assist Mr. Anderson was by the granting of a sum of money towards the expenses of the actions. Mr. Rivington proceeded to recount the particulars of the severe persecution to which Mr. Anderson had been subjected, mentioning that the colonial judge had decided that a medical man had no right to retire from a case under any circumstances. The whole colony had suffered under a tyranny in the form of law, and Mr. Anderson had been sent to England by the colony to bring the matter before the home authorities. In an action in the Queen's Bench Division against the judges of the colony Mr. Anderson had received a verdict in his favour, with £500 damages; but the judge had given judgment against him, saying that a judge could not be proceeded against for a judicial act. A commission was sent out to Trinidad by the Government, with the result that the judges implicated were suspended. In England the Civil Rights Defence Committee was formed, and in 1894 the Council had appointed two representatives on that committee. Mr. Anderson could not practise in Tobago until the judgements which had been given against him were reversed. The Council could assist Mr. Anderson in obtaining justice only by a grant of money. It was true that there was no precedent, but there were very few other cases to which the by-laws could apply. Mr. Anderson would be utterly ruined if the Council did not give assistance, and a few hundreds would add greatly to the reputation of the College as a vindicator of the rights of the profession.

Mr. TIMOTHY HOLMES seconded the resolution.

Mr. CHRISTOPHER HEATH said that while he sympathised very deeply with Mr. Anderson he thought that his cause had got into bad hands. Mr. Anderson was being used as an instrument by which the Council might be attacked. It was an unheard-of thing that a member of the Council should try to force the hands of the Council in this way. The meeting of Fellows had no power to force the Council to do an illegal act, and it would be illegal to advance money for such a purpose. He was no longer treasurer of the College and so it did not affect him, but if he were treasurer nothing would induce him to sign a cheque for such a purpose. He was astonished that Mr. Holmes, who was treasurer of St. George's Hospital and had to deal with public funds, should support such a resolution. The Council were asked to act against their common sense. The by-law did not bear the construction put upon it by Mr. Rivington. It was true they had appointed two representatives on the Civil Rights Defence Committee, but it was more out of good nature than anything else.

Mr. JENNINGS asked what Mr. Anderson's legal advisers said about the chance of a favourable judgment in the House of Lords.

Mr. ANDERSON replied that his own legal advisers said that they thought the action would be successful in the House of Lords, and as to the appeal to the Privy Council no one had any doubt whatever as to its success.

Mr. HOLMES expressed his great surprise at the manner in which he had been attacked by Mr. Heath. Of course, if it were certainly illegal to advance College funds for such a purpose no one would ask it. But was it illegal? Mr. Heath had declared it to be illegal, but he thought it desirable to have the decision of someone whose opinion on legal matters was of a little more value than Mr. Heath's. The solicitor of the College had declared it to be illegal, but he had expressed a similar opinion as to the holding of meetings of the Fellows apart from the Members and he had been mistaken. He considered it very desirable to have counsel's opinion on the matter.

Mr. ANDERSON said that the by-law would be reduced to an absurdity if it were illegal for the Council to use the College funds for this purpose.

Sir ROBERT CRAVEN expressed his opinion that it was time that the subject was closed. The subscribing of funds for such a purpose was a matter for the profession and not for the Council.

Mr. RIVINGTON rose to reply, but the Secretary pointed out that only twenty-nine Fellows were present, and the Chairman declared the meeting at an end.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6938 births and 4084 deaths were registered during the week ending Jan. 9th. The annual rate of mortality in these towns, which had been 17·0 and 22·3 per 1000 in the two preceding weeks, declined again last week to 19·4. In London the rate was 18·5 per 1000, while it averaged 20·0 in the thirty-two provincial towns. The lowest rates in these towns were 10·8 in Croydon, 12·5 in Brighton, 15·1 in Derby and in Leicester, and 15·8 in Hull; the highest rates were 22·7 in Manchester, 23·0 in Plymouth, 25·2 in Bolton and in Leeds, and 23·6 in Liverpool. The 4084 deaths included 415 which were referred to the principal zymotic diseases, against 279 and 436 in the two preceding weeks; of these, 103 resulted from diphtheria, 98 from whooping-cough, 85 from measles, 53 from scarlet fever, 40 from diarrhœa, and 36 from "fever" (principally enteric). No death from any of these diseases was recorded last week in Croydon; in the other towns they caused the lowest death-rates in Brighton, Bolton, Norwich, and Burnley, and the highest rates in Birmingham, Newcastle-upon-Tyne, Birkenhead, Plymouth, and Nottingham. The greatest mortality from measles occurred in West Ham, Portsmouth, Plymouth, Nottingham, Bradford, and Newcastle-upon-Tyne; and from whooping-cough in Swansea, Birmingham, Nottingham, and Blackburn. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 103 deaths from diphtheria included 71 in London, 7 in Birmingham, 4 in Leicester, 3 in Birkenhead, 3 in Liverpool, and 3 in Leeds. No fatal case of small-pox was registered last week in any of the thirty-three

Hosted by Google

large towns. There were 2 small-pox patients under treatment in the Metropolitan Asylum Hospitals on Saturday last, the 9th inst., against 3 at the end of the preceding week; no new cases were admitted during last week. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 3597, against 3868, 3763, and 3707 on the three preceding Saturdays; 290 new cases were admitted during the week, against 291, 219, and 271 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 284 and 348 in the two preceding weeks, declined again last week to 335, and were 379 below the corrected average. The causes of 60, or 1·5 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Hull, Newcastle-upon-Tyne, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in Leicester, Liverpool, Blackburn, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased in the six preceding weeks from 20·3 to 22·4 per 1000, further rose to 22·8 last week, and was 3·0 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 18·4 in Aberdeen and 18·6 in Greenock to 25·9 in Glasgow and 32·4 in Perth. The 680 deaths in these towns included 45 which were referred to measles, 20 to whooping-cough, 17 to diarrhœa, 10 to scarlet fever, 6 to "fever," and 3 to diphtheria. In all, 101 deaths resulted from these principal zymotic diseases, against 106 and 103 in the two preceding weeks. These 101 deaths were equal to an annual rate of 3·4 per 1000, which was 1·4 above the mean rate last week from the same diseases in the thirty-three large English towns The fatal cases of measles, which had been 54, 48, and 60 in the three preceding weeks, declined again to 45 last week, of which 41 occurred in Glasgow. The deaths referred to whooping-cough, which had been 26 and 15 in the two preceding weeks, rose again last week to 20, of which 14 were recorded in Glasgow and 4 in Edinburgh. The 10 fatal cases of scarlet fever exceeded the number registered in any recent week, and included 5 in Glasgow, 2 in Edinburgh, and 2 in Aberdeen. The deaths referred to different forms of "fever," which had been 4 and 3 in the two preceding weeks, rose again to 6 last week, of which 2 occurred in Glasgow, where 2 of the 3 fatal cases of diphtheria were also recorded. The deaths from diseases of the respiratory organs in these towns, which had been 152 and 151 in the two preceding weeks, were 152 last week, and exceeded by 17 the number in the corresponding period of last year. The causes of 58, or more than 8 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 26·5 and 44·1 per 1000 in the two preceding weeks, declined again to 35·2 during the week ending Jan. 9th. During the fourteen weeks of last quarter the death-rate in the city averaged 27·6 per 1000, the rate during the same period being 18·1 in London and 17·8 in Edinburgh. The 236 deaths registered in Dublin during the week under notice showed a decline of 60 from the number in the preceding week, and included 40 which were referred to the principal zymotic diseases, against 21 and 36 in the two preceding weeks; of these, 19 resulted from whooping-cough, 9 from measles, 5 from "fever," 4 from scarlet fever, 3 from diarrhœa, and not one either from small-pox or diphtheria. These 40 deaths were equal to an annual rate of 6·0 per 1000, the zymotic death-rate during the same period being 1·8 in London and 1·6 in Edinburgh. The fatal cases of whooping-cough, which had increased from 4 to 23 in the four preceding weeks, declined again to 19 last week. The deaths referred to measles, which had been 2 and 5 in the two preceding weeks, further rose to 9 last week. The 5 deaths from different forms of "fever" showed a further increase upon recent weekly numbers, and the 4 deaths from scarlet fever also exceeded the numbers registered in recent weeks. The 236 deaths in Dublin last week included 31 of infants under one year of age and 54 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a decline from the high numbers recorded in the preceding week. Seven inquest cases and 4 deaths from violence were registered; and 81, or more than a third, of the deaths occurred in public institutions. The causes of 21, or nearly 9 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING DECEMBER, 1896.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during December in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious disease in the metropolis during last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 10·7 per 1000 of the population, estimated at 4,421,955 persons. In the three preceding months the rates had been 14·5, 14·6, and 12·6 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in St. George Hanover-square, St. James Westminster, Westminster, St. Pancras, Strand, City of London, and Plumstead; while they showed the largest excess in Clerkenwell, St. Luke, Bethnal Green, St George-in-the-East, Poplar, St. George Southwark, St. Olave Southwark, and Lewisham. Three cases of small-pox were notified in London during December, the cases having declined from 41 to 0 in the six preceding months. There were 3 cases of small-pox under treatment in the Metropolitan Asylum Hospitals at the end of November, against 4, 2, and 1 at the end of the three preceding months; 3 new cases were admitted during the month. The prevalence of scarlet fever in London showed a further decline from that recorded in recent months; this disease was proportionally most prevalent in Islington, Hackney, St. Martin-in-the-Fields, Clerkenwell, Bethnal Green, St. George Southwark, and Battersea sanitary areas. The Metropolitan Asylum Hospitals contained 3601 scarlet fever patients at the end of November, against 3847, 4054, and 3932 at the end of the three preceding months; the weekly admissions averaged 355, against 412, 398, and 356 in the three preceding months. The prevalence of diphtheria in London showed a further slight decline from that recorded in the two preceding months; among the various sanitary areas this disease showed the highest proportional prevalence in Chelsea, St. Luke, Whitechapel, St. George-in-the-East, Mile End Old Town, St. Olave Southwark, Camberwell, Lewisham, and Woolwich. There were 829 diphtheria patients under treatment in the Metropolitan Asylum Hospitals at the end of December, against 774, 780, and 777 at the end of the three preceding months; the weekly admissions averaged 119, against 116, 105, and 110 in the three preceding months. The prevalence of enteric fever in London showed a further decline from that recorded in recent months; this disease was proportionally most prevalent in Kensington, Hackney, City of London, St. George-in-the-East, Mile End Old Town, Battersea, and Lee sanitary areas. Erysipelas showed the highest proportional prevalence in Holborn, St. Luke, Shoreditch, Poplar, St. Saviour Southwark, and St. George Southwark sanitary areas. The 24 cases of puerperal fever notified during December included 6 in Islington, 4 in Greenwich, and 3 in Camberwell sanitary areas.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas, the deaths occurring in the institutions of London having been distributed among the various sanitary areas in which the patients had previously resided. During the five weeks ending Saturday, Jan. 2nd, the deaths of 7482 persons belonging to London were registered, equal to an annual rate of 17·6 per 1000, against 14·5, 16·5, and 19·2 per 1000 in the three preceding months. The lowest death-rates during December in the various sanitary areas were 10·4 in St. Martin-in-the-Fields, 12·2 in Plumstead, 12·7 in Lee, 12 7 in Hampstead, 14·0 in Stoke Newington, 14·4 in Wandsworth, and 14·7 in Fulham; the highest rates were 22·6 in Holborn, 22·9 in Limehouse, 23 4 in St. George-in-the-East, 23·5 in St. Saviour Southwark, 23·9 in St. George Southwark, 25·4 in Strand, and 26 9 in St. Luke. During the five weeks of December 647 deaths were referred to the principal zymotic diseases in London; of these, 255 resulted from diphtheria, 123 from whooping-cough, 92 from scarlet fever, 71 from measles, 56 from enteric

fever, 48 from diarrhœa, and 2 from ill-defined forms of continued fever. These 647 deaths were equal to an annual rate of 1·5 per 1000; no fatal case of any of these diseases occurred last month in St. James Westminster; among the other sanitary areas the lowest death-rates from these diseases were recorded in Westminster, St. Giles, St. Martin-in-the-Fields, Bethnal Green, St. Saviour Southwark, and Lee; and the highest rates in Clerkenwell, St. Luke, Limehouse, Mile End Old Town, St. George Southwark, Newington, St. Olave Southwark, and Bermondsey. No fatal case of small-pox was registered in London during December, and it is now six months since a death from this disease was recorded within the metropolis. The 71 deaths referred to measles were less than a fifth of the corrected average number in the corresponding periods of the ten preceding years; this disease was proportionally most fatal in St. Luke, Limehouse, Mile End Old Town, Poplar, and Rotherhithe sanitary areas. The 92 fatal cases of scarlet fever were 26 below the corrected average number; among the various sanitary areas this disease was proportionally most fatal in St. Giles, Clerkenwell, St. Luke, and Newington. The 255 deaths from diphtheria exceeded by 37 the corrected average number; this disease showed the highest proportional fatality in St. Luke, Whitechapel, St. George Southwark, St. Olave Southwark, Bermondsey, Camberwell, and Woolwich sanitary areas. The 123 fatal cases of whooping-cough were little more than half the corrected average number; among the various sanitary areas this disease was proportionally most fatal in Holborn, Clerkenwell, St. Luke, St. George Southwark, Newington, and Lewisham. The 56 deaths referred to enteric fever were 30 below the corrected average number; this disease showed the highest proportional fatality in Mile End Old Town sanitary area. The 48 fatal cases of diarrhœa were 23 below the corrected average number. In conclusion, it may be stated that the mortality in London during December from these principal zymotic diseases was more than 43 per cent. below the average.

Infant mortality in London, measured by the proportion of deaths of children under one year of age to births registered, was equal to 131 per 1000, and was below the average. Among the various sanitary areas the lowest rates of infant mortality were recorded in St. James Westminster, St. Martin-in-the-Fields, City of London, St. Olave Southwark, Battersea, and Plumstead; and the highest in Kensington, Hammersmith, Stoke Newington, Strand, Holborn, St. George-in-the-East, and St. Saviour Southwark.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-MAJOR J. L. HALL has been ordered to Woolwich for duty. Surgeon-Captain Russell has proceeded to Gibraltar. Surgeon-Major T. Dorman, M.D., has been ordered to Queenstown for duty. Surgeon-Major E. A. Roche proceeds to the Curragh for duty. Surgeon-Major Trewman and Surgeon-Lieutenants Perry, Staddon, and J. Walker, M.B., have been warned to embark at Southampton for Bombay.

The following promotions are announced: — Brigade-Surgeon-Lieutenant-Colonel Napoleon B. Major to be Surgeon-Colonel; Surgeon-Lieutenant-Colonel W. L. Gubbins, to be Brigade-Surgeon-Lieutenant-Colonel; and Surgeon-Major John G. S. Lewis, from half pay, to be Surgeon-Major. Surgeon-Colonel Ferguson, who lately joined at Woolwich from India, has become Principal Medical Officer on the staff of Major-General J. F. Maurice, C.B., commanding the Woolwich district, and he has succeeded Surgeon-Colonel Price, who lately went to India. Surgeon-Colonel Ferguson can only hold his new post at Woolwich about a couple of years, as he will then have to retire on reaching the age of sixty years. He has been nearly thirty-five years in the army, and took part in the Bhootan Expedition of 1864, Afghan War of 1879, and Egyptian Campaign of 1882.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Captain W. J. Buchanan, Officiating Superintendent of the Bhagalpur Central Gaol, is appointed to act as Civil Surgeon of Burdwan, during the absence of Brigade-Surgeon-Lieutenant-Colonel W. H. Gregg. Surgeon-Captain B. C. Oldham, Officiating Superintendent of the Midnapur Central Gaol, is appointed to act as Deputy Sanitary Commissioner, Metropolitan and Eastern Bengal Circle. Surgeon-Major Henry Hearsey Bathe, East Indian Railway Volunteer Rifle Corps, is appointed Surgeon-Lieutenant-Colonel. The services of Surgeon-Captain H. B. Melville, M.B., C.M. (Bengal), are placed permanently at the disposal of the Government of the North-Western Provinces and Oudh. Surgeon-Captain E. Wilkinson, whose services have been placed at the disposal of the Government of the Punjab, has arrived at Lahore and has been appointed to officiate as Civil Surgeon of Karnal. Surgeon-Lieutenant-Colonel W. H. Cadge, Civil Surgeon, Naini Tal, has been appointed to the Medical Charge of the camp of his Honour, the Lieutenant-Governor and Chief Commissioner, North-Western Provinces and Oudh, and Surgeon-Major A. E. Tate, A.M.S., has been appointed to the Civil Medical Charge of the Naini Tal District, in addition to his military duties. The undermentioned Surgeon-Lieutenants appointed to the Bengal and Madras Establishments, have arrived at Bombay:—*Bengal:* H. J. Walton, H. Ainsworth, H. A. D. Dickson, and J. S. Stevenson. *Madras:* J. W. Cornwall, A. Miller, H. R. Brown, W. G. Richards, S. P. James, A. N. Fleming, P. Dee, F. O. N. Mell, F. D. Browne, and M. Dick. Surgeon-Captain Kebel, A.M.S., who recently left India for Paris for treatment at the Pasteur Institute, is progressing satisfactorily and hopes to return to India soon. Surgeon-Captain L. T. M. Nash, A.M.S., and Surgeon-Lieutenant J. M. Buist, A.M.S., have been posted to the Punjab Command. Surgeon-Captain M. P. Holt, A.M.S., and Surgeon-Lieutenant C. K. Morgan, A.M.S., have been posted to the Bombay Command.

NAVAL MEDICAL SERVICE.

The following appointments are announced: — Fleet Surgeons: A. Patterson to the *Edinburgh;* E. H. Saunders to the *Blake;* and Valentine Duke to Devonport Dockyard. Surgeons: E. H. Meadow to the *Egeria*, and S. H. Youel to the *Penguin*.

VOLUNTEER CORPS.

1st Devonshire (Western Division, Royal Artillery): Surgeon-Lieutenant W. A. Payne, M.B., resigns his commission. *Royal Engineers (Volunteers):* 1st Devonshire and Somersetshire: Thomas Smith, gent., to be Surgeon-Lieutenant. *Rifle:* 3rd Lanarkshire: Surgeon-Lieutenant T. Forrest, M.B., to be Surgeon-Captain. 4th Volunteer Battalion the Cameronians (Scottish Rifles): Surgeon-Lieutenant G. McIntyre, M.B., to be Surgeon-Captain. 5th Volunteer Battalion the Cameronians (Scottish Rifles): Surgeon-Captain J. Blair, M.D., resigns his commission; James Kirkland, gent., to be Surgeon-Lieutenant.

DEATHS IN THE SERVICES.

Among the deaths in the Services we regret to record that of Surgeon-General M. F. Manifold (retired), of the Army Medical Department, in connexion with whose name it is to be remembered that the employment of female nurses in the army in Ireland during the great famine year took place owing to the prevalence of small-pox in the garrison. Miss Florence Nightingale found in the late officer a warm supporter at Scutari, where he had charge of the officers' hospital during the Crimean War. Surgeon-General Manifold was the son of the late Major John Manifold, and received his commission as Assistant Surgeon in the 77th Regiment in 1846. After the campaign he was promoted for his services and was appointed to the 34th Regiment, with which he served during the Indian Mutiny in the pursuit of Nana Sahib. Later he attained administrative rank, and at the time of his retirement held the post of Surgeon-General at Netley.

The death is announced of Brigade-Surgeon J. S. Conyers, M.D. Edin. (retired), in Demerara on the 20th ult. He joined the Army Medical Service in 1868 and retired in 1884, after having served in the Ashanti War of 1873–74, and was present at the engagements of Amoaful and Ordahsu, the capture of Beequah and Kumasi.

Surgeon-Major Manser, of the Indian Medical Service, whose death from plague at Bombay was recently reported, has lost his life from his devotion to his professional duties. He entered the Indian Medical Service in 1877 and was promoted Surgeon-Major in 1889. He was nearly forty-seven years of age at the time of his death. In 1879 he served in the Afghan War and took part in the defence of Kandahar. He had also occupied the posts of Professor of Medicine and Therapeutics at Grant Medical College

Hosted by Google

and First Physician of the Jamsetjee Jeejeebhoy Hospital, Bombay. The European nurse who attended the late Surgeon-Major Manser during his fatal illness has since died from plague, having, in all probability, also contracted the disease in the execution of her duty.

Dr. Thomas Jameson, eldest brother of Dr. Leander Starr Jameson, died on New Year's Day at his residence in Knollys-road, Streatham, where he was in practice. He was fifty-nine years old. He graduated M.D. at Edinburgh University in 1858, in which year he also obtained the Licence of the Royal College of Surgeons of Edinburgh. He became a Surgeon in the Royal Navy on Aug. 20th, 1858, was promoted to be Staff Surgeon on Nov. 29th, 1869, and retired on April 10th, 1872. Dr. Jameson was in receipt of a pension for wounds.

CIVIL SURGEONS IN BENGAL.

A notification appears in the *Calcutta Gazette* of Dec. 16th, 1896, announcing that, in accordance with the orders of the Government of India in the Home Department, No. 910, dated Oct. 19th, 1896, sanctioning the abolition in Bengal of the present classification of civil surgeons by stations and the substitution in its place of a personal classification under which the higher emoluments now given for the charge of first-class stations will be granted to commissioned medical officers according to seniority and merit without regard to the stations at which they may be employed, the Lieutenant-Governor is pleased to order that the following medical officers shall, with effect from Dec. 1st, 1896, draw the higher emoluments hitherto attached to the six first-class civil stations, Bengal: Brigade-Surgeon-Lieutenant-Colonel W. H. Gregg, Brigade-Surgeon-Lieutenant-Colonel C. J. W. Meadows, Surgeon-Lieutenant-Colonel J. M. Zorab, Surgeon-Lieutenant-Colonel Russik Lal Dutt, Surgeon-Lieutenant-Colonel G. Price, Surgeon-Major A. W. D. Leahy. Officers drawing the higher allowance will in future be styled civil surgeons of the first class, all others being styled civil surgeons of the second class.

THE NEWS FROM WEST AFRICA.

There seems unhappily to be little doubt that the disastrous news from Benin of the massacre of a British expedition is true. The expedition started on a perfectly peaceful mission and unarmed from the coast by way of Sapele to Benin city. According to a Reuter's telegram the Consul-General's yacht *Ivy* brought the intelligence to Bonny that the expedition, with the native followers, had been surprised and massacred by the King's people. Among the names of those who are supposed to have perished we sincerely regret to notice that of the medical officer of the expedition, Dr. R. H. Elliott. The mission to the King of Benin was apparently an important one, as the acting Consul-General, his Deputy-Commissioner, the Commandant of the Niger Coast Protectorate Force, and others accompanied it. Benin city lies about sixty miles inland from the mouth of the River Niger. This treacherous conduct of the King of Benin will no doubt lead to a punitive expedition against him and his people.

AMBULANCE SHIPS IN THE UNITED STATES NAVY.

It is proposed to add ambulance ships to the navy of the United States. The new ships will be fast unarmoured steamers of three decks, fitted with large wards and operating rooms. Each squadron of men-of-war going into action would be accompanied by one ambulance ship, which would gather and collect the wounded during, and after, the conflict and convey them to a distance, where, in comparative safety and quietness, they would receive treatment. Such ships will doubtless be rendered easily distinguishable by means of shape, colour, and flags, and it may confidently be trusted will be respected as far as possible by the combatants.

THE INDIAN TROOPS FROM SUAKIN.

The Indian contingent to Suakin has returned, of course, to India after having had a monotonous and trying time of it in that very hot and uninteresting station. The accounts of the outbreak of scurvy among the troops at Suakin seem to have been somewhat exaggerated, for the number of severe cases was relatively small, although a mild form of the disease was very prevalent among the sepoys and native followers.

ARMY MEDICAL SCHOOL.

The Netley examination for surgeons on probation passing out of the Army Medical School will commence on Friday, Jan. 22nd, and terminate on Thursday, Jan. 28th. The results will be promulgated on Saturday, Jan. 30th, when the Director-General of the Army Medical Department will preside.

THE NIGER COMPANY CAMPAIGN.

The force proceeding on this expedition consists of Hausa troops, with Maxim guns and twenty-six officers, under Major Arnold, two surgeons, and 900 carriers, to march against the Foulah forces at Kabbar, south-west of the Niger.

ROYAL VICTORIA HOSPITAL, NETLEY.

Notification has been received that Surgeon-Captain I. Paterson, M.B. Edin., A.M.S., will arrive at Netley for duty on the 5th proximo.

The Director-General of the Army Medical Staff and Mrs. Jameson, Major-General and Mrs. Maurice, Surgeon-Colonel and Mrs. Ferguson, Surgeon-Colonel and Mrs. Fawcett, and many other officers were present during one of the series of Christmas and New Year entertainments held at the Herbert Hospital, Woolwich.

It has been decided that officers of the Army Medical Staff will be viewed as on separate lists for each of the four Commands in India. Officers of the Indian Medical Service will be viewed as on separate lists for the Madras and Bombay Commands, but collectively as on one list for the Bengal and Punjab Commands.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund, held on Jan. 12th, Dr. W. H. Lloyd, Inspector-General, in the chair, the sum of £85 was distributed among the several applicants.

An examination of candidates for thirty-five commissions in the Army Medical Staff will be held at the Examination Hall, Victoria Embankment, W.C., on Feb. 5th and following days.

Correspondence.

"Audi alteram partem."

MEDICAL FEES IN CORONERS' COURTS.

To the Editors of THE LANCET.

SIRS,—In an annotation in THE LANCET of Jan. 9th you refer to an inquest held by me on Jan. 3rd at Croydon Hospital, when the acting house surgeon declined to reveal the results of his post-mortem examination unless I paid him the fee and until (in answer to his query) I informed him that the consequence of his refusal would be his committal for contempt of Court. I do not wish to deal with this individual case, though acquiescing in your opinion that it was an "incident to be regretted," for the gentleman subsequently apologized for his ignorance of the Law. Such incidents occur from time to time, and it is matter of regret and surprise to me that in most of our text-books on Forensic Medicine no mention is made of the rights and duties of medical men in coroners' courts. You observe that "it is strange that it is not universally known by this time that a medical man who has attended a patient at a hospital, workhouse infirmary, or other public institution—the death having occurred in such place—cannot recover fees for making a post-mortem examination or for giving evidence at an inquest." But even your description is hardly in accordance with the present practice of some coroners—myself among them—who have taken advantage of an exposition of the law a little more favourable to our profession. As the matter is frequently referred to in your correspondence columns, perhaps you will allow me to state the law and practice as at present existing. The law as to "fees to medical witnesses" in a coroner's court is laid down in the 22nd section of the Coroners' Act, 1887, wherein a guinea is awarded for "attending to give evidence at any inquest," and also a guinea "for making a post-mortem examination;" but, "provided that where an inquest is held on the body of a person who has died in a county or other lunatic asylum, or in a public hospital, infirmary, or other medical institution, or in a building or place belonging thereto, or used for the reception of the patients' thereof, whether the same be supported by endowments or by voluntary

Hosted by Google

subscriptions, the medical officer whose duty it may have been to attend the deceased person as a medical officer of such institution as aforesaid shall not be entitled to such fee or remuneration."

Amongst coroners there is but one interpretation of these words—viz., that house surgeons are not entitled to such fee. Such "medical officers" are explicitly excluded from the privilege of claiming a fee by the words, "a public hospital," and again by the phrase, "a medical institution—supported by endowments or by voluntary subscriptions." But coroners differ in their practice as to medical officers of workhouse infirmaries. These infirmaries are not supported "by endowments" or "by voluntary subscriptions," but by the rates, and of these there is no mention. Hence, a year or two ago, Mr. Poland, Q.C., gave it as his opinion that medical superintendents of workhouse infirmaries and their assistants were entitled to fees. As soon as I became aware that this was the judgment of so eminent a lawyer, I at once wrote to our town clerk, himself a solicitor, and asked him to consider the matter with the Recorder and to authorise me, if they could accept Mr. Poland's interpretation of the Act, to pay the usual fees to Mr. Wilson, the medical superintendent of our infirmary, who had wisely brought the matter to my notice. And I am glad to say that with their approval from that time I have paid the medical officers of our workhouse infirmary the fees which other medical practitioners receive. All such medical officers elsewhere may well try to persuade their coroners that it has been held by a high authority that they are entitled to fees; but it is surely time that students, ere they leave their hospitals, should be informed that if they seek house-surgeoncies they must be prepared to undertake all the duties of the position and that it is unwise to make demands that coroners, however friendly to them, must firmly refuse.

I am, Sirs, yours sincerely,

THOMAS JACKSON, J.P.,
Coroner for Croydon.

Thornton Heath, Jan. 11th, 1897.

"POST-PARTUM HÆMORRHAGE AND ITS TREATMENT."

To the Editors of THE LANCET.

SIRS,—I am glad to see, both from an article by Dr. Laird in THE LANCET of Sept. 19th, 1896, and from several letters I have received, that the question of post-partum hæmorrhage and its treatment has excited some interest. Most of the letters I have received speak of the method I have advocated with approbation and confidence; one writer, however, agrees as to its value, but considers it a secondary measure, manual compression, injections, &c., apparently holding a primary place in importance. I cannot help thinking that if he discovered a leak in a water pipe in his house from which water was pouring he would have no great opinion of the plumber who on being called in should say: "As a *primary* measure we will dab some putty on this hole and as a *secondary* one we will turn off the main tap."

Some weeks ago a correspondent, signing himself "Rinaldo," wished to know if Davy's lever was used in these cases. May I point out to him that it is of the utmost importance in a matter of this kind, when every moment is of importance, that we should not be dependent upon any instrument which may or may not be there, but that each man should be able at once to control the hæmorrhage, as Hans Breitmann would say, "mit dose dings dat God has gave him." But the most serious contributor to the subject is Dr. Laird and I ask for a little of your valuable space in which to reply to him. In the first place, he will, I am sure, admit that all analogies break down if you push them too far. If he will read my paper again he will see that I never intended the illustration I gave to stand as a parallel in all points; and, indeed, he admits that it stands good "in the sense in which I applied it." However, this is not the main point. If I understand Dr. Laird rightly he advocates pressure near the entrance of the arteries into the uterus. I notice that he does not say how often he has carried out this plan or what were the results. Indeed, he speaks in the old doubtful way about it—"Should bleeding not then be fully controlled"; "the pressure on the arteries may be applied *probably* with better effect," &c. (the italics are mine); and it is this very doubtful tentative condition of mind that, I submit, should be absolutely eliminated when face to face with so serious a condition, so immediate a danger.

Let us consider the method itself. You are to "pass the right hand into the womb ..... to close it, and with the left hand compress the uterine and ovarian arteries against it on either side, the fingers grasping the left side and the thumb the right side." I presume that Dr. Laird seriously means what he says, but it is difficult to understand how the thumb can control two distinct arteries, the one entering at the top and the other at the neck of the uterus. Even if we grant this to be possible when the uterus is small and contracted, how is it to be done in these cases, the essential characteristic of which is that there is little or no contraction, but the uterus is a widely dilated flabby mass filling, in some cases, more than half the abdomen? The power of knowing what is going on, which Dr. Laird claims "as one of the great advantages of this plan," I fully recognise, but it is not necessary, I conceive, that we should *feel* the gushing blood to recognise its presence. Blood is being poured out either into the dilating uterus or through the vagina into the open. If the latter, we can see it; if the former, the hand pressed down upon the aorta above it would be equally conscious of the increasing bulk below. I say would be, because I have never found bleeding to go on when once the aorta was controlled, and therefore can only speak of the sensation given to the hand frequently of a big sloppy mass when compression is commenced. One need not speak of the quick, running pulse, the white, sweating face, the deep, gasping respirations, because these will occur to everyone. Dr. Laird is very anxious about the effect of "practically stopping the blood supply to half the human frame," which I admit is done by the method of aortic compression. From personal experience I can assure him he need not be; but even theoretically there is nothing in the objection. Pressure by far rougher means has been kept up for far longer periods than is here required for aneurysm of the common iliac, the external iliac, and the femoral arteries, and the blood has been shut off an extremely long time by Martin's bandage and a tourniquet in osteoplastic and other operations. It is of the utmost importance to remember which half of the human frame is kept empty and which half is thereby kept full by this manœuvre. The full half contains the essentially vital organs and the empty half contains nothing absolutely essential to life. Were the upper half to lose a sufficient supply the nervous centres of respiration and of circulation cease to act. It is not sufficient that they should have some blood; they must have enough. If they cease it will not matter much whether the patient has legs or not. But practically I have never seen anything worse follow than some coldness, numbness, and paresis of the muscles, which is never more than temporary, except the usual tingling, which may even be painful when the current returns. Is this a heavy price to pay for life?

I confess I cannot follow Dr. Laird or the authorities he refers to in their dread of regurgitation from the vena cava. On what observations or even constituent theory does it rest? Why should it regurgitate? If the patient were erect and walking about it might be possible, but if the foot of the bed is properly lifted the patient is in the directly opposite position. Why should the blood in the vena cava which up to now has always flowed in the direction nature originally marked out for it now all at once turn round and walk the other way? If there were compression of the cava above it would be conceivable, but no veins bleed to any extent if there is free passage for their contents towards the heart and gravity assists, and here there is no obstacle; indeed, the laboured efforts of the heart to fill itself sufficiently tend to empty the cava away from the uterus rather than to overfill it. The whole idea is to me incomprehensible. Moreover, experience, the final test, proves that there is nothing in it. I am glad that Dr. Laird is directing his attention to this subject, but I am sure that the further he follows it up and the more cases he sees the more he will agree with me that we ought all to have one plain, positive dictum based on common consent and common sense, upon which we can all act at once without any doubt or vacillation.

I am, Sirs, yours faithfully,

G. STANMORE BISHOP.

St. Ann's-square, Manchester, Jan. 9th, 1897.

"TRADES UNIONISM AND THE MEDICAL PROFESSION."

To the Editors of THE LANCET.

SIRS,—A "blackleg" may be described as one who may not only refuse to join with his fellows in a demand for higher wages or in resisting additional burdens to his labour,

Hosted by Google

but takes advantage of the temporary or threatened cessation of work to sell his labour at a lower rate than his fellows. There is a spirit of antagonism as well as a meanness in the action of such a man, and consequently he comes to be looked upon not merely as a passive objector to their schemes of reform, but as an enemy in their camp. In their contest with the friendly societies medical men are in the position of the employed, and when anything like competition exists professional conduct sinks so low that men will be found to offer tenders for their services. It is generally assumed that medical appointments are made upon the principle of merit and personal fitness, except in some cases, as we all know, where patronage or favouritism of some kind exerts its influence. It is not assumed, however, that medical men shall barter their services after the manner of ordinary commercial contracts. With the growth of coöperation and combination exemplified in the trades unions and the various friendly societies there have developed strained relations between the medical profession and certain public bodies having medical appointments. This has of late become acute in the case of appointments to some of the friendly societies.

Now, it must be borne in mind that the individual practitioner is quite unable to make terms of a satisfactory character against the combined forces or the combined influence of the friendly societies. It is still more hopeless if he has to compete with other medical men for these appointments. What is the remedy? Obviously there is but one course to pursue. The profession must combine and by combination and coöperation lay down certain lines upon which the services of its members may be obtained. Its members must be compelled, either by written or unwritten law, to refuse anything lower than the standard which has been adopted as consistent with professional dignity and honour. Such practices as canvassing and touting by agents must be severely punished. Private medical clubs recruited by the assistance of a collector and canvasser must be abolished. Tendering for an appointment must be considered unprofessional conduct. If men be allowed unrestricted competition with each other against the solid and powerful influence of large corporations and societies the standard of fee will be kept low and some members of the profession will hardly earn a living wage. Are the Yarmouth and Beckenham societies going to succeed by importing blacklegs, or will the legitimate and reasonable demands of the doctors at both these places be acceded to? The new movement so far as the profession is concerned consists essentially in efforts at combination and coöperation. Some of the successful members of the profession dislike the term "trades unionism." They are fortunate to have been able to do without it. It is, however, but another name for collectivism and involves the principles of combination and coöperation. The old adage "United we stand — divided we fall" merely expresses it in different language. What is now wanted in the profession is organisation. Where is the central authority which can take up the interests of the general practitioner and can at the same time compel obedience to its mandates? Except for a few favoured ones the medical profession as a method of business—as a means of earning more than a respectable pittance in life—is a miserable calling. And it must continue so until the wretched terms and the low fees which a large number of struggling men have felt themselves compelled to make shall be improved by legislation protecting the profession from its own suicidal impulses.

I am, Sirs, yours faithfully,

T. FREDERICK PEARSE, M.D. Brux.,
Jan. 4th, 1897. Hon. Secretary, Portsmouth Medical Union.

THE HALF-YEARLY MEETING OF THE FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

To the Editors of THE LANCET.

SIRS,—Believing that the friendly interchange of views between the Fellows of the Royal College of Surgeons of England and the Council would materially assist in the solution of the difficulties attending the prosecution of Mr. Anderson's appeals I consented to move at the last half-yearly meeting of the Fellows the following mild and inoffensive resolution:—

"That this meeting submits to the Council that no objection can apply to an advance from the funds of the College to prosecute Mr. Anderson's appeal to the Privy Council, and therefore trusts that the Council will sanction a grant for that purpose."

In support of this resolution it was necessary to prove (1) that Mr. Anderson had been disturbed in his rights as a Fellow and Member of the College; (2) that under By-law XV. the Council had undertaken to protect and defend Mr. Anderson from such disturbance; and (3) that the only effective way in which the Council can fulfil its obligations is by a grant of money for the promotion of Mr. Anderson's appeal to the judicial committee of the Privy Council to obtain the reversal of the illegal orders and judgements which prevent him from returning to Tobago. Mr. Heath, who followed me, elected to treat my friendly resolution as an attack upon the Council. In addition, however, Mr. Heath made certain statements which I am anxious now to correct because they may have been accepted as facts by some of the Fellows present, and because the untimely end of the meeting from the lack of the requisite quorum of thirty prevented me from exercising the right of a reply which I had just commenced when the Chairman closed the proceedings.

Mr. Heath stated that the Council had on two occasions already negatived the proposal in the resolution; that its adoption would be illegal; and that an opinion to that effect had been given by the solicitor of the College. Mr. Heath has not been careful to distinguish between two distinct appeals—one to the House of Lords and the other to the Privy Council. The appeal to the House of Lords was taken up by the Civil Rights Defence Committee after the Council of the College had appointed representatives on that committee. To this appeal the Council has twice declined to make any grant, and though I voted against the resolution adopted by the Council I fully admit that in the appeal to the House of Lords the professional element is overshadowed by the civil element, and that the obligations of the Council in regard to it are constructive and not very apparent. With regard to the appeal to the Privy Council the position is very different. In June, 1894, Lord Stamford asked the Council to appoint representatives on the Civil Rights Defence Committee to promote this appeal, and Mr. Anderson claimed the protection of the College under By-law XV. The solicitor of the College was consulted, and gave it as his opinion that the by-law was not applicable to Mr. Anderson's case, but he went on to say: "The decision that he was not at liberty to discontinue his attendance on a patient when he thought fit is one which seriously affects the medical profession, and I do not think the College would be exceeding their legal rights in assisting him to obtain the reversal of such decision." On the motion of Mr. Morris, seconded by myself, the Council decided to appoint two representatives on the committee to forward the appeal to the Privy Council. In seconding the motion I stated that I did so because I dissented from the solicitor's opinion and considered Mr. Anderson's claim under the by-law unimpeachable, and from this position I have never receded. As Mr. Anderson's case now stands my experience during the past year convinces me that it is absolutely essential to the success of his appeals that the College should head a list of subscriptions. A subscription of £200 only would exercise an enormous influence on Members of Parliament and others who now hold back because the College only affords moral support; and if the Council would appoint a committee for the reception of subscriptions and dealing with the funds other bodies would contribute Mr. Anderson would be in good hands and success would be assured. To meet Mr. Heath's objections all that is necessary is that the Council should submit the proposed grant to a general meeting of Fellows and Members for approval, in accordance with the principle that the Fellows and Members should be consulted with regard to extraordinary expenditure.

There is one personal matter on which I must say a few words for the justification of others. Mr. Heath challenged a passage in the address of my recent election committee, which stated that I had used every advantage which I possessed as a Fellow, *even to the sacrifice of my collegiate interests*, to advance the claims of the Members to representation on the Council. He then said that this must refer to the time, nearly six years, during which I had been on the Council, that it was an improper statement for a member of the Council to inspire, and was refuted by the fact that I had never during the period applied for any appointment in the gift of the Council. The words in italics to which Mr.

Hosted by Google

Heath objected were perfectly correct and refer to the year 1886. The fact that I have not applied for any appointment since I have been a member of the Council should have been sufficient in itself, without other considerations, including the wording of the passage, to convince Mr. Heath that the words in italics could not possibly refer to the period of my tenure of office as a member of the Council. I shall only add that if I had continued to apply for appointments in the gift of the Council after I became a member of that body I should have belied the statement in my election address to the Fellows—"that I came forward for the Council, not to advance any interest of my own, but to assist in making the College more useful to the Fellows, the Members, and the profession at large."

I am, Sirs, yours faithfully,

Wimpole-street, Jan. 9th, 1897. WALTER RIVINGTON.

"ALLEGED ARSENICAL POISONING."

To the Editors of THE LANCET.

SIRS,—Dr. Murrell has again misrepresented me. The facts are not so "perfectly simple" as he states in his second letter.[1] I leave Dr. Bernard Dyer to give his version of his evidence in "Bennett *v.* Grant," being aware that he is quite able to satisfactorily explain his analysis. It is of Dr. Murrell's strictures on myself that I have reason to complain. He says: "We are told that Dr. Stevenson cannot detect $\frac{1}{20}\frac{1}{00}$th of a grain of arsenic." For this statement there is no foundation. What I did say at the trial was that a square foot of the linenette yielded no indubitable evidence of the presence and amount of arsenic, and I defined what I meant by indubitable evidence. This, I said, meant sure evidence by several tests that arsenic was present, and also that the quantity could be approximately estimated. No mere stain obtained by Marsh's test satisfies my requirements of proof. When half a square yard of the linenette was operated on I obtained conclusive evidence of the presence of arsenic and of the quantity present—viz., $\frac{1}{20}\frac{1}{00}$th of a grain, or $\frac{1}{10}\frac{1}{00}$th of a grain per square yard. These results accord with the experience of Dr. Luff, the late Professor Wormley, Otto, and others, who give $\frac{1}{50}\frac{1}{00}$th to $\frac{1}{33}\frac{1}{00}$th of a grain of arsenic as the quantity of arsenic yielding satisfactory evidence. I succeeded with $\frac{1}{20}\frac{1}{00}$th of a grain but failed to detect $\frac{1}{50}\frac{1}{00}$th of a grain in the linenette. The remark of Dr. Murrell that "the difference between ..... $\frac{1}{200}\frac{1}{00}$th of a grain and $\frac{1}{50}\frac{1}{00}$th of a grain," has no bearing upon the question in dispute. As to the delicacy of the tests for arsenic I may state, what I have often deposed, that when the arsenic is mixed with much organic matter the detection and estimation of 1 part of arsenic in 1,000,000 is nearly always reliable, but that when the proportion is much less the results are not always reliable. Of course, when in a pure form very much less than $\frac{1}{50}\frac{1}{00}$th of a grain may yield satisfactory evidence of its presence.

I am, Sirs, yours faithfully,

Jan. 12th, 1897. THOS. STEVENSON.

To the Editors of THE LANCET.

SIRS,—My attention has been called to the correspondence in THE LANCET referring to the case in which Dr. Stevenson and I recently gave evidence. I think undue stress has been laid on the difference between the numerical expression which we respectively gave to our results. What substantially happened was that Dr. Stevenson, working by one process, found what would ordinarily be described as a "small trace" of arsenic, while I, working by another process, found what would ordinarily be described in such a case as a "considerable trace."

Dr. Stevenson employed Marsh's test, using half a square yard of the "linenette," and decomposing the arseniuretted hydrogen by heating the tube, depositing the mirror in the tube by cooling, in the usual way. Under some circumstances, not yet well defined, there is in my experience some degree of uncertainty in Marsh's test, when it is relied upon for the *quantitative* estimation of such very minute quantities of arsenic as these; and though by this test Dr. Stevenson did not obtain more than the $\frac{1}{10}\frac{1}{00}$th of a grain of arsenic per square yard of the material, it does not necessarily follow that this was the whole of the small quantity of arsenic present. I say this as the result of numerous experiments of my own, in which known minute quantities of arsenic have been added to the Marsh apparatus under different circumstances and with different kinds of zinc. Indeed, in the Chemical Society's Proceedings some years ago I drew attention to the fact that when "rod" or "cast" zinc is used very appreciable quantities of arsenic may sometimes be even wholly obscured. On the other hand, it was clearly explained in evidence and understood by the judge that my own figure was the result of a crude estimate formed from the appearance of the sulphide of arsenic precipitate obtained after distilling a square foot of the material with arsenic-free hydrochloric acid. It did not presume to be an accurate estimate, but was rather given as an outside limit. The material was only submitted to me hurriedly on the eve of the trial of the action, for which action, I may observe, my report was not responsible.

While I think Dr. Stevenson's numerical estimate may have been somewhat low it is quite possible, on the other hand, that my own estimate may have been somewhat high owing to some admixture of free sulphur in the small precipitate, although the latter was twice dissolved in ammonia and re-precipitated by acid. Qualitatively, however, I may say that I found no difficulty in obtaining from a piece of the material four inches by eight inches a distinct mirror by the Marsh test, using re-agents so pure that in an hour's "running" alone they had given no mirror; while, on the other hand, a piece of the material four inches square quite failed to give any deposit on copper in Reinsch's test. The question of how small a quantity of arsenic can be recognised, separated, and correctly estimated obviously depends upon a variety of circumstances, such as the form in which the arsenic exists and the nature and quantity of the material amongst which it is diffused, as well as upon the process of analysis employed. The quantitative errors of estimation incidental to the recognition of very infinitesimal quantities sink, however, in experienced hands, into comparative insignificance whenever arsenic is present in anything approaching a materiai proportion; but when only traces are present, diffused in much organic matter, errors of estimation which are absolutely small appear relatively great, and assume numerically a greater apparent significance than really attaches to them.

Reported evidence is not always satisfactory, and if Dr. Murrell had actually heard the "linenette" case I do not think he would have attached so much importance to the discrepancy between Dr. Stevenson's estimate and my own as he has on reading the report. At all events, I think that the impression of the judge was that Dr. Stevenson's evidence and my own were, for all practical purposes, in agreement. The original supposition, as stated in the evidence of the lady's medical attendant, was that the "linenette" was coloured with a copper-arsenic pigment, such as Scheele's green, in which case the arsenic would presumably have been found in grains, and not in minute fractions of a grain per square yard.—I am, Sirs, yours faithfully,

BERNARD DYER, D.Sc., F.I.C.

Great Tower-street, E.C., Jan. 13th, 1897.

MORPHOLOGY OF THE TETANUS AND TUBERCLE BACILLI.

To the Editors of THE LANCET.

SIRS,—Referring to your report of Dr. Kanthack's interesting demonstration at the Pathological Society on Jan. 5th,[1] permit me to point out that the belief in the existence in the tetanus bacillus of a terminal flagellum only, as propounded by Schwarz, is not accepted by the most recent writers of the German school. Lehmann and Neumann, in their work published last year, refer to the flagella in the following terms, and the note of exclamation is theirs: "Eigenbewegung gering oder fehlend trotz zahlreicher langer peritricher Geisseln. Nach Schwarz nur 1 endständige Geissel!" In the discussion which followed I maintained that the branching forms of the tubercle bacillus had been first described by MM. Nocard and Roux, but Dr. Kanthack persisted in the statement that these forms were first described by Dr. Klein. I will, therefore, give the quotation to which I referred:—"Dans une culture vieille de plusieurs mois nous avons rencontré des formes renflées plus longues qu'à

[1] THE LANCET, Jan. 6th, 1897.

Hosted by Google

l'ordinaire, quelques unes d'entre elles présentaient comme un bourgeon latéral branché presque à angle droit sur le bacille principal et terminé quelquefois par un renflement à son extrémité."[2] I am quite aware of Dr. Klein's remarks and of Mr. Pringle's photographs in the Nineteenth Annual Report of the Local Government Board, 1889-1890 (Plate XXVII.) but for the sake of historical accuracy I should be glad if Dr. Kanthack would either publish in your columns the date of any researches prior to those made by my friends MM. Nocard and Roux in 1886-87, or on the other hand verify my statement. I may add that I confirmed Nocard and Roux's observations in cultures obtained direct from human tuberculous sputum.[3]

I am, Sirs, yours faithfully,
EDGAR M. CROOKSHANK.

Saint Hill, East Grinstead, Jan. 9th, 1897.

"THE TRAINING OF NURSES IN RELATION TO REGISTRATION."

To the Editors of THE LANCET.

SIRS,—Permit me briefly to reply to Dr. Biernacki. I have done so at some length on a previous occasion and only a few words are necessary now. It is to do away with the very grievance Dr. Biernacki complains of (to prevent anyone posing as a nurse without sufficient training) that the proposal to register properly trained and qualified mental nurses has been brought forward, and thus to carry out one of the most important objects for which the Royal British Nurses Association was formed—viz., that it should act as a protection both for the public and the nurse. With regard to the paragraph in the *Hospital* he will find it fully dealt with in admirable letters by Dr. Ernest White and Miss East, late lady superintendent to the National Hospital for the Paralysed and Epileptic, Queen-square, W.C., in this week's issue of that paper. I maintain that it is the duty of the Royal British Nurses Association to register these mental nurses as such; I hold that the charter of the association is dead against any such narrow policy as Dr. Biernacki has been led to believe was either the letter or the spirit of that Royal Charter. I thoroughly agree with his concluding paragraph as to "what this confusion between incompletely and fully trained nurses means to the medical profession and the public one has only to look round to realise," and it is after looking round and realising that the medical profession is being convinced it has a right to demand that all nurses employed by the public who are qualified either by asylum or by hospital training shall be registered. We who have to deal largely with nervous and mental diseases know the value of mental nurses, and we ask, and the public has a right to ask, that the Royal British Nurses Association shall act up to its charter and, under certain conditions, place them upon its register. I can assure Dr. Biernacki nothing will be done to unduly force this matter on, time and calm deliberation will prove the value of the proposal I advocate, and from what I know of his fairness and courtesy I have every confidence that ere long he will think as I do.

I am, Sirs, yours faithfully,
T. OUTTERSON WOOD, M.D. Durh.,
Member of the Executive Committee and of the Registration Board of the Royal British Nurses Association.

Margaret-street, Cavendish-square, W., Jan. 11th, 1897.

"THE PARASITE OF MALARIA."

To the Editors of THE LANCET.

SIRS,—The following notes of my observations of the blood in malarial fever in West Central Africa may perhaps interest some of your readers. I commenced this work in September, 1895, and from that time until I left my station on furlough on June 30th, 1896, I examined the blood for parasites over forty times. Excluding my first two examinations in every case of fever, both in European and natives, I succeeded in discovering parasites. Once or twice I succeeded in finding the parasite when headache was the only symptom, but twice when I suspected such symptoms as diarrhœa were due to malaria I failed to find it. My examinations were all with a $\frac{1}{12}$th-inch lens and an ordinary eye-piece, with Beck's student's microscope tube pulled out to its furthest limit. I fully carried out instructions as to examination of fresh specimens, and was very much disappointed in finding no pigmented bodies like those described by Dr. Laveran, Dr. Marchiafava, and others. On my third investigation my attention was directed to some of the red corpuscles manifesting slight oscillatory movements and occasionally rolling over. As they lay flat hardly any difference was noticeable in their outline, but in profile an irregularity in outline was at once detected, one side being straight and on the other side it was convex.

In February a fellow missionary fell ill of malaria, a severe form associated with hæmoglobinuria, which proved fatal. In this case I made daily observations and fully expected to find some different form of parasite. I only found the bodies of the same character, but they were very numerous. The case was fatal in five days. The blood corpuscles before death became exceedingly scarce and the plasma distinctly coloured with hæmoglobin. With my microscope I could not discern the spore when first it attacked the corpuscle; it was apparently too small for my object-glass. I could only suspect it by the suspicious movement of the corpuscle above mentioned. When mature and sporulated the parasite was nearly as large as a red corpuscle. The absence of pigment in these parasites is to me very interesting, as in the part of West Central Africa where I have been stationed for over seven years I have seen no case of melanæmia. Not having, however, had opportunities of making necropsies, I have unfortunately not been able to examine the organs of the body. The splenic enlargement often reaches the umbilicus and is always soft to palpation. The fevers show no regular form, varying in length from a few hours to several days, and a daily variation may or may not be present. Jaundice is sometimes present without hæmoglobinuria, but hæmoglobinuria is always accompanied by jaundice, which is no doubt secondary to the immense amount of free hæmoglobin floating in the plasma.

I am, Sirs, yours faithfully,
WALTER FISHER, M.R.C.S. Eng., L.R.C.P. Lond.

Kavungu Lovale Country, near Upper Zambesi, W. Central Africa.

THE VENTILATION OF HOUSE DRAINS.

To the Editors of THE LANCET.

SIRS,—At a meeting of the urban district council to which I am medical officer of health I suggested this addition to the by-laws—viz., "that the owner of each new house should construct a ventilating intercepting trap to disconnect the house drains from the sewer," but one of the council stated that the district was too flat and the fall for drainage not enough to permit such a course. The district is a flat one and I do not think any of the drains are disconnected. There are no ventilators in the centre of the streets and the only ventilation is by a few soil-pipes carried up here and there and by a 6-in. pipe at the pumping station carried up 20 ft. high; the sewage is pumped to the sewage farm one mile away. Will you kindly say if these conditions are a bar to the employment of intercepting traps, and, if not, should I be doing my duty by bringing forward the subject again and quoting your opinion? I may mention that I have only been recently appointed or should have brought this matter to the fore sooner.

I am, Sirs, yours truly,
Jan. 6th, 1897. BAYNHAM.

*** Without a knowledge of the depth and size of the sewer in the road and the probable distance from the same to the highest point of the house drains it is impossible to give a definite reply to our correspondent's question, but the following particulars may be of service. For a disconnecting trap to act efficiently it should have a fall into it from the drain of six inches, either as a direct cascade or as described on p. 47 of the reprint of THE LANCET Special Commission to inquire into the Relative Cost and Efficiency of Plumbers' Work. The house drains should have a fall of at least 1 in 60. It is certainly desirable, with a sluggish and ill-ventilated sewer such as is described, that something should be done to relieve the pressure of drain

[2] Sur la culture du Bacille de la Tuberculose. Annales de l'Institut Pasteur, Janvier, 1887.
[3] Transactions of the Pathological Society, 1891.

Hosted by Google

air from the house drains and traps. With reference to ventilation there is a general impression that a ventilator does not exercise any effect upon the air in sewers beyond 500 feet from the point of insertion; 300 feet away is a common distance for road ventilators. It might, if the houses are situated near together, be more desirable, as an alternative, that each house should carry up a separate ventilating pipe of not less than four inches in diameter (see By-law 4, L.C.C.) to a suitable height. This pipe to be inserted into the drain at a point near to where the drain leaves the premises; there should also be another similar ventilator at the extreme or highest end of the house drain. By this means the pressure of air would be relieved from the house drains. Of course the fact of only a few isolated houses ventilating the sewer, by means of their soil pipes, is obviously very unsatisfactory. If all sewers had an even fall throughout, and were properly flushed and well ventilated, the air in them would be far less objectionable than is commonly the case. One great point is to keep the sewage on the move.—ED. L.

"ARMY EXAMINATIONS."

To the Editors of THE LANCET.

SIRS,—Your annotation on "Army Examinations" in THE LANCET of Jan. 9th is, I think, open to much criticism. The situation is this. For each vacancy in the army there are a large number of candidates and selection is made by competition on certain lines. Whether these lines are judiciously ordered is a point on which great differences of opinion exist. You cannot, however, get rid of the competition. If you make physique a leading feature you will eliminate men of the build of Lord Wolseley and Lord Roberts. If athletics are brought to the front you will soon create a special class of men engaged in training youths for special feats. The fact is that in our large public schools the special education required interferes greatly with the general school studies. Further, there cannot be that individual attention given to each boy which is so essential. The clever or diligent youth or the one who has been put into a proper groove by a thoughtful parent is successful, as at the University of London, whilst the duller and lazier and ill-prepared ones are unsuccessful. The latter leave school and, with those entering the army through the militia, are taken in hand by special instructors, whom it is a gross injustice to stigmatise as "crammers." These instructors, by force of character and experience, by careful study of each individual, and with the assistance of a staff of highly trained assistants, succeed by genuine solid work in many instances where schoolmasters have failed. For years the military authorities have striven to meet the schoolmasters in every possible way, but still the "crammers" survive, and assuredly will continue to fulfil a need. Now the worsted schoolmasters seek the power of nominating candidates. Whether it is desirable to admit officers who are not gifted with very good brains or who are naturally lazy is another question. The candidates passing through the hands of "crammers" are not inferior in physique or athletic accomplishments to others, and you have only to inspect a parade of Sandhurst cadets to see that the present system does not unduly stimulate the brains of the officers at the expense of their bodies. If London is objected to as an educational centre, then there are lots of instructors who live in the country. In such a place I have often seen poor "etiolated doctrinaires" playing cricket, football, lawn tennis, and other games, and each with his bicycle or polo pony or dog-cart; and in the ample vacation I believe hunting and other sports are not neglected.

I am, Sirs, yours faithfully,

Jan. 9th, 1897. PHYSICIAN.

BEQUESTS TO HOSPITALS.—The Rev. Charles Fellowes has bequeathed to the Norfolk and Norwich Hospital £100 and to the Jenny Lind Infirmary £50.—The secretary to th e Victoria Hospital for Children has received promises of 1000 rupees each from the Maharajah of Bhartpur and the Nawab of Bahawalpur towards the *fête* to be held in June next for the benefit of the hospital.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Health Lectures.

DR. W. H. LINE delivered one of a series of lectures under the auspices of the Midland Institute on the 11th inst. before an appreciative audience. He took for his subject the Breath of Life: Pure Air and How to Get It. The Chairman of the Health Committee, Alderman Cook, presided, and in the course of his remarks congratulated the city upon the decline of scarlet fever and some other diseases, and spoke of the advantages to be gained from the number of parks and open spaces. The work of the Health Committee, he observed, was a responsible and arduous one, which was carried out with zeal and energy for the good of the inhabitants. The lecturer was warmly applauded and thanked at the close of the lecture.

Charity Ball.

In aid of the funds of the Birmingham and Midland Counties Hospital for Women a large and brilliant gathering assembled to enjoy themselves on the evening of the 8th inst. The reception was held by the Viscountess Newport—the Lady Mayoress of the city—and Mrs. Chamberlain. The gathering was in every way a success. About 800 tickets were disposed of, giving a sum of £840, while some £460 was received in donations. It is stated that £1700 is required to place the hospital in a sound financial position for the time being. There ought to be no difficulty in a wealthy community like this in raising this sum for so worthy an object. The generous public will have another opportunity shortly of contributing a larger sum towards the completion of the new General Hospital, when the committee intends to appeal for an extra £40,000 for the completion and equipment of the building.

Improvement Scheme.

At a meeting of the town council a proposal by the Improvement Committee to build artisans' dwellings in a certain area and to borrow £6250 for the purpose was rejected by a large majority. Free criticism was expended upon the plans, which were said to contain many infractions of the by-laws with regard to health requirements, and from a financial point of view the project was condemned with equal firmness and determination. While giving the committee credit for the desire to establish some relief in the way of accommodation for this class, it was clearly shown that their proposals would have to be modified considerably before being accepted.

Jan. 12th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Liverpool Stipendiary on the Administration of the Oath.

MR. F. A. STRINGER'S recent letter to the *Times* alluding to the mode of administering the oath in courts of justice and to the dangers attached to kissing a dirty Testament has excited comment in the local press. The subject-matter of the letter is quite in accord with the recorded opinions of the medical profession, and although it must be looked upon as ancient history by the readers of THE LANCET, in the columns of which the subject has been treated in leading and other articles many years ago, yet Mr. Stringer's letter is very welcome and will strengthen the efforts of those who have been advocating the abolition of the uncleanly practice of "kissing the book." In December, 1892, Mr. F. W. Lowndes brought the question to the notice of the members of the Liverpool Medical Institution, and proposed three resolutions which were unanimously carried, the first of which pointed out the dangers of kissing a book in indiscriminate use. The second resolution was to the effect that it was desirable to have the permission to swear with uplifted hand brought to the notice of every juror, witness, and persons required to take an oath; also that copies of those resolutions be sent to the local stipendiary magistrate, the city coroner, and to the press. Speaking from the bench of the Liverpool Police-court last week Mr. Stewart, the stipendiary magistrate, referred to

Hosted by Google

the subject, and said that ever since he had sat on that bench any person who desired to take the oath in the Scotch form was always permitted to do so, and if at any time any officer whose duty it was to administer the oath had not had an opportunity of administering it in that way before he had personally administered. Very shortly after the passing of the Act the form of the oath was printed upon a slip of paper, and every officer whose duty it was to administer the oath in that court was furnished with the Scotch form of the oath. It is to be hoped that after these remarks of the stipendiary any witness who desires to be sworn in the Scotch form may be allowed to do so without that preliminary "chaff" which has been indulged in by those whose duty it is to carry out the law and not to ridicule it.

Allegations against a Birkenhead Medical Man.

An inquest was recently held at Birkenhead touching the death of a young coachman aged eighteen years, who died after a few hours' illness. The deceased complained of pains in his head and back. He went to bed, and in the evening of the same day Mr. A. S. Clarke was sent for and prescribed a draught composed of bromide of potassium and chloral. About midnight the deceased became worse, when Mr. Clarke was again summoned. While Mr. Clarke was in the house Mr. G. S. Stansfield was also sent for, who remarked that the young man was dying. According to the evidence of Mr. Stansfield this statement was resented by Mr. Clarke, who replied: "He is not dying; he will be all right. I warn you not to touch my patient. He is my patient." Mr. Stansfield thereupon replied: "The man is dying either from cerebral mischief or from poison." Another witness named Thomas Leyland deposed that when he returned home in the evening he saw the deceased in bed. He was breathing heavily and witness went for Mr. Clarke. A druggist named Joseph Corkson stated that the deceased came to his shop on Saturday and complained of pains in his head and back, and said he could not sleep. Witness gave him a draught of antipyrin and also a bottle containing camphor liniment with which to rub his back. The bottle produced had had very little of the liniment taken from it. Deceased attributed the pains to lifting heavy boxes. Mr. T. R. Jones stated that he made a post-mortem examination of the body of the deceased. There was a slight effusion of blood on the left side of the brain, but not sufficient to account for death. The stomach was much inflamed and presented the appearance of having contained an irritant poison. He concluded that death had resulted from poison, but how administered or what it was he did not know. The quantity of lotion taken from the bottle would not have affected him so even if he had taken it. Mr. Arthur S. Clarke deposed that he was asked to see the deceased on the Saturday night, who, he was informed, was in bed raving. Witness questioned the deceased, but his replies were very incoherent. He had a dread of light and wished to be in the dark. Witness returned to his surgery and made up a draught for deceased consisting of bromide of potassium and chloral. He entered the prescription in his book. He was again called to the house about midnight, when deceased was sleeping heavily, but there was nothing to show immediate danger. The draught was a little below the usual strength and would not set up inflammation. The jury returned a verdict that deceased died from the effects of an irritant poison, but how it was taken or administered there was no evidence to show. The jury were satisfied that the draught given by Mr. Clarke was not poisonous.

The Health Committee and Dairies.

The Health Committee have formulated a new code of regulations for the conduct of dairies which have been ratified by the city council. These require efficient lighting, at least 600 cubic feet of air space for each cow, the internal walls and ceilings to be limewashed twice a year, dung to be removed twice a day, effective drainage, and compulsory notification of any infectious disorder among the persons occupying the premises.

Hospital Sunday.

Collections were made under very unfavourable circumstances in the churches and chapels in the city on Sunday last on behalf of the Hospital Sunday Fund. The morning was raw and cold. The snow which fell during the greater part of the previous day had left the ground in a sloppy condition and largely interfered with the attendance at the various places of worship. It is open to question whether the early part of January, when wintry weather must be expected, is the most suitable month for this collection. Archdeacon Madden, preaching at St. Luke's Church, only echoed the sentiments of many in lamenting the adherence of the Hospital Sunday Committee to the January fixture. He considered that April or May would be more suitable for many reasons. It is feared that the collections, although not all completed, will fall short of those made at the same period of last year.

Hospital Accommodation at Seacombe.

The deficiency of hospital accommodation in the Seacombe and Wallasey districts is engaging the attention of the Wallasey Urban District Council. Dr. Napier, a member of the council, considers that a central hospital is desirable, and suggests a conference between a sub-committee of the district council and the joint committee of the Seacombe Hospital and the Wallasey Dispensary to report on the subject. It is expected that a sum of £6000 will be required to meet the expense of enlarged hospital accommodation for these districts.

The Proposed New Hospital for Phthisis.

After much deliberation the committee of this hospital have decided to first take in hand the building of a branch hospital in the country to accommodate twenty beds, and subsequently to pull down the present houses in Mount Pleasant and build a hospital for the reception of forty patients. In order to carry out the scheme suggested the committee wish it to be known that a sum of £50,000 will be required. Mr. William Rathbone, formerly member of Parliament for Liverpool, is the president of the hospital and is taking an active part in promoting the new scheme. It is probable that West Kirby, which enjoys a most salubrious climate, will be the selected suburb.

Superannuation of Poor-law Officers.

The select vestry of the parish of Liverpool have resolved that, in consequence of the recently-passed Poor-law Superannuation Act, it is of importance that in making fresh appointments the vestry should be satisfied as to the age and state of health of the candidates. This resolution is a reasonable one, and will equally apply to medical candidates for office in the parish of Liverpool.

Jan. 12th.

WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Bristol.

THE committee of the Bristol Dispensary, in their statement of accounts for the past year, report that the work of the institution has been carried on in a highly satisfactory manner. The receipts from subscribers show a slight reduction from the previous year. The premises designed for the branch dispensary at Bedminster are now in course of erection, and during the present year will be ready for the accommodation of patients. This branch dispensary will be of much advantage to those living in Bedminster. A large sum has already been expended on the building, but before its completion £1400 will be required, which will necessitate the selling of some investments. The committee appeal for donations towards this fund.—At the meeting of the Barton Regis board of guardians held on Jan. 1st the chairman stated that during 1896 there had been 3349 admissions to the workhouse and 3266 discharges; 39 children were born in the house and 116 inmates died. It had only been necessary to punish one inmate and to proceed against one in-door pauper before the magistrates; the master had also only inflicted punishment once. This shows that with an average of 1000 in the house only three persons had in the year been guilty of conduct which deserved punishment.—From the report presented at the last meeting of the Barton Regis board of guardians it appears that there are now 156 unvaccinated cases. At the beginning of the past quarter the number was 76. At a meeting of the Horfield urban district council held on Dec. 29th.

Hosted by Google

it was decided to erect an isolation hospital at Patchway. The cost of the building will be £5000 and it will contain twelve beds. Horfield, which is practically a northern suburb of Bristol, has long felt the want of a hospital for infectious diseases, and it is satisfactory to see that at last such a building is to be erected.—Mr. Bancroft will give a reading of "The Christmas Carol" on Jan. 28th, the proceeds of which will be given to the Bristol Royal Infirmary. The Duke of Beaufort has consented to preside.—The collection on Hospital Saturday in Bristol amounted to £810, but this is separate from the proceeds of the week's amateur theatrical performance in aid of the hospitals, which account is not yet closed.—A handsome brass lectern has just been placed in Hook's Mills Orphanage Chapel, at Bristol, as a memorial to the late Alderman Charles Highett, M.R.C.P. Edin., who died on April 20th, 1896, and who had been a guardian of that asylum for fifteen years. The lectern is of an artistic character, the figure of the eagle being especially fine.

Cheltenham Town Improvement Committee.

At the monthly meeting of the Cheltenham town council, held on Jan. 4th, Mr. G. H. Ward-Humphreys, M.R.C.S. Eng., L.R.C.P. Lond., on behalf of the Town Improvement Committee, introduced a scheme, the cost of which is estimated at £50,000, for the erection of a "kursaal" and the conversion of the present winter-garden building into municipal offices and a palm conservatory. In an exhaustive speech he reviewed the various schemes which had been suggested for facilitating the use of the mineral waters and providing a spa. Various reasons were adduced in favour of the present scheme devised by Mr. Ward-Humphreys, the borough surveyor, and an architect. As to the spa he contended that local medical men were unanimously in favour of it, and a bright future for Cheltenham had been predicted if the scheme were carried out. Mr. Ward-Humphreys had the subject of his speech thrown upon a screen by limelight. It was eventually decided that the matter be adjourned, but it is hoped that the scheme will be passed and the mineral waters of Cheltenham will be more extensively used than they are at present.

Ambulance Classes in Gloucestershire.

At the quarterly meeting of the Gloucestershire Standing Joint Committee held on Jan. 4th, the chief constable, in applying for a further sum for the St. John Ambulance Classes, reported that 239 of the constabulary, which is rather more than half of the force, now hold certificates of that society, and five members of this constabulary were successful in winning the challenge shield of the Gloucester Ambulance Association on Dec. 3rd.—At the Gloucestershire Quarter Sessions on Jan. 4th the chairman stated that the report of the visitors of the Inebriates Retreat at Kingswood near Bristol was most satisfactory, and the home was, he thought, of advantage to the county. He also stated that the report of the visitors with reference to the private lunatic asylums at Northwood and Fairford showed that these institutions were well conducted.

Barry Accident Hospital.

At a meeting of the executive of the Barry District Nursing Association held on Dec. 29th, 1896, under the presidency of Mr. George Neale, J.P., L.R.C.P. Edin., the honorary treasurer presented a report showing that practically the association would be in debt to the extent of about £300 at the close of the year; and after considerable discussion it was decided, as the continuance of the accident hospital would entail a loss of about £400 per annum, to call a meeting of the subscribers on Jan. 21st, when a resolution will be submitted stating that the association has found that the maintenance of the accident hospital is too great a tax upon its resources, and that it is therefore desirable that the Barry Urban District Council should be asked to undertake its maintenance and control.

Appointment at Devonport Dockyard.

The Admiralty have selected Fleet Surgeon Valentine Duke, B.A., M.B., for the Devonport Dockyard appointment, as successor to Fleet Surgeon M. F. Ryan. For the past three months Dr. Duke has held an appointment on the *Thunderer* for Dockyard service at Pembroke, previously to which he served in the *Hibernia* at Malta. It is not likely that he will retain the Devonport appointment for the full three years, as he has eleven years' seniority as Fleet Surgeon and in a few months may reasonably expect to obtain the rank of Deputy-Inspector-General of Hospitals and Fleets.

Jan. 12th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Pollution of Scottish Rivers.

DR. JOHN GLAISTER, Professor of Forensic Medicine and Public Health in St. Mungo's College, Glasgow, delivered an address on this subject to the Glasgow Philosophical Society on the 6th inst. After reference to the extensive pollution of rivers in consequence of the enormous development of trade processes and the establishment in populous centres of the water-carriage system of sewerage, he discussed the direct and indirect consequences of such pollution and proceeded to review the various legislative Acts dealing with the subject. Dr. Glaister enumerated the recommendations of the Royal Commission of 1876, which reported after a period of four years spent in examining the principal streams of Great Britain; he then proceeded to point out how the Rivers Pollution Prevention Act, based upon the Commissioners' report, had been a failure. This failure he attributed to the absence from the Act of a standard of purity for effluents or discharges and to the non-prescription of penalties for contravention. The restrictions introduced for the purpose of protecting trade interests had in practice seriously interfered with the value of the Act, so that it had been for years practically a dead letter, and the principal streams of the country are, as a consequence, as foul as, or even fouler than, when the Commission reported. Dr. Glaister advocated the institution of steps by which the Act of 1876 could be amended, and referred to the success which had attended the local powers obtained by the Lancashire and Yorkshire county councils. He especially advocated a legal definition of the standard of purity for discharges. This was recommended by the Commission of 1876 and was endorsed by Liebig and Dumas, the latter proposing to phrase the definition as follows: "Whenever water was so affected by a town or manufacture as to become unfit for supporting the life of fish or of green plants, the pollution, from whatever cause derived, should be considered an insupportable nuisance from whatever cause arising." In addition to such a standard Dr. Glaister argued that the provisions of an amended Act should be compulsory, that committees representing the counties interested should be formed for river cleansing, and that inspectors charged with the duty of supervising the methods of purifying effluents and preventing the entrance of new sources of pollution should be appointed. In support of the latter provision he quoted the success which had attended a similar step in preventing gaseous contamination of the atmosphere by the powers of the Alkali Act. The time, Dr. Glaister contended, was ripe for these reforms, and a determined attempt should be made to press them upon Parliament. The address was illustrated by means of maps of the principal Scottish rivers, which showed the source and incidence of the polluting discharges, and by lantern slides. Dr. Ebenezer Duncan, president of the society, presided.

Scientific Lectures.

On the 8th inst. Professor Cleland lectured in the Corporation Galleries, Glasgow, on the Artistic Treatment of the Human Figure. Professor Cleland argued for the necessity of accurate representation, which could only be attained by a study of the capabilities of the human frame. He insisted upon the importance of giving attention to posture in relation to balance both in the representation of rest and action and described the different forms of the head and face as these vary according to race, sex, and age. The lecture was listened to by a large audience, and upon the proposal of Bailie Shearer a cordial vote of thanks was awarded to Professor Cleland. Lord Kelvin on the 11th inst. delivered in the University of Glasgow the first of a series of free public lectures to be given by members of the Senate. His subject was: "The Molecular Dynamics of a Crystal."

Glasgow Medico-Chirurgical Society.

At the January meeting, on the 8th inst., Dr. Walker

Hosted by Google

Downie gave a practical demonstration of the use of Kirstein's "autoscope" in the examination of the larynx. Dr. J. K. Love read a note on the History of Gliomatosis and Syringomyelia; and Professor Joseph Coats demonstrated with the projection microscope a number of slides illustrating the conditions and prepared from four cases by Dr. Love.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Small-pox in Dublin.

AT the meeting of the guardians of the South Dublin Union, held on the 6th inst., the clerk stated that he had received a notice from the office of Sir Charles Cameron that there was a case of small-pox in the city. He telephoned immediately to all the city hospitals, but could obtain no accommodation for the case, which it was accordingly considered best to leave at the patient's residence, while every precaution possible to compass isolation was adopted. After an interview with Sir Charles Cameron and Mr. Stafford, the Local Government Board inspector, he also inquired of the authorities at Cork-street Fever Hospital whether, in the event of the guardians taking over twenty convalescent patients, they would be prepared to allocate a ward for the treatment of this or any other case of small-pox that might arise. Dr. Day, the resident physician at Cork-street Hospital, was in attendance, and stated that his hospital would receive small-pox patients under the conditions mentioned. Mr. Stafford, reported that the patient with small-pox had probably contracted the disease from a brother who had recently returned from South Africa and been exposed to the contagion on his way home. He also stated that the residents at the house had been protected by re-vaccination and a sanitary officer placed on duty to prevent persons entering or leaving the house until such time as the case could be removed to hospital. After some discussion the board passed a unanimous resolution as follows:—

"That the attention of the Local Government Board be called to the fact that the joint action of the boards of both the Dublin unions during the past two or three years, to provide a permanent hospital for cases of infectious disease, has resulted in the conviction that a portion of the Pigeon House building lately purchased from the Government by the corporation would be eminently suitable for the purpose. The chairman of the board of guardians of the South Dublin Union was authorised to make arrangements for purchase of the building required, but the matter is delayed by the fact that the corporation have not yet got possession of the property. Having regard to the urgent necessity of procuring a hospital without delay the board request the Local Government Board to make such representations to the Government and the corporation as will bring the negotiations to a speedy completion so as to facilitate the boards of both unions in getting possession of the buildings so much required."

A very strong letter has appeared in the *Freeman's Journal* from Professor Antony Roche, in which he complains, and apparently with much reason, that the sanitary authorities should now propose to make Cork-street Hospital again a small-pox centre of infection for the South City, as it certainly had proved to be on the occasion of the last epidemic—a fact, he says, which was demonstrated by Sir Charles Cameron's maps of the distribution of the disease.

Surgeon-Major Beevor on Ashanti.

Surgeon-Major Beevor of the Scots Guards delivered a most interesting lecture on Saturday afternoon at the Ancient Concert Hall in the presence of His Excellency the Lord-Lieutenant, the Countess Cadogan, and a distinguished audience. The lecture, which was given in aid of the Soldiers and Sailors Families' Association, was entitled, "The Ashanti People, their Manners, Customs, and Wars," and was fully illustrated by means of lantern slides as well as by a large collection of native articles brought home by the lecturer and his brother officers after the late expedition.

The late Sir George Owens, J.P.

At the meeting of the committee of the Meath Hospital, held on Monday last, the following resolution was proposed by Sir William Porter, Bart.: "That at this the first meeting of the committee since the lamented death of our esteemed friend and valued colleague, Sir George Owens, J.P., we desire to express our deepest regret at the loss of one who for a period of nearly thirty years was one of the most active governors of the hospital, and whose kind and genial disposition had endeared him to all the members of the board as well as to the various officials, and we desire to convey to his son, Colonel Owens, and the other members of his family our deep and sincere sympathy with them in their sorrow, as we place on record our warm appreciation of his long and valued services to the hospital."

The New Belfast Hospital.

About £50,000—that is, one half of the sum required for the new hospital—has already been promised, and on the invitation of the Lady Mayoress (Mrs. Pirrie) a very large meeting of ladies was held in the City Hall on Jan. 12th, when, after some admirable speeches, a large general committee of ladies was appointed, who are to select ten ladies of their number who are to be members of the executive committee, and who are to act along with the gentlemen and to have the same place and powers.

Irish University Education.

The Irish University question is again being very freely discussed at present, and a very strong demand has been made during his recent visit to Ireland by the Lord Chief Justice of England (Lord Russell of Killowen) and by Mr. Justice O'Brien for a Roman Catholic university. The latter judge at a meeting on Jan. 11th in Dublin, said that £50,000 a year ought to be granted for the maintenance of a Catholic university in Dublin, and as this university was not to be a mere examining board, but an institution devoted to the complete control of youth in its education, social advancement, and religion, the sum of £250.000 was, he said, what many considered the least amount Parliament could grant for the establishment of a Catholic university.

The Belfast Asylum.

The report on the Belfast Asylum of Dr. O'Farrell, Inspector of Lunatics, has just been published. He says that all restraint appliances should be retained in the charge of the medical officers and used only by their direct instruction, and that there should be daily and accurate entries of every case in which restraint or seclusion has been employed. The condition of the auxiliary asylum at Purdysburn Dr. O'Farrell regards us most satisfactory. He thinks it the most beautiful site and surroundings for an asylum in the United Kingdom, and he refers to the announcement of the new asylum during 1897 as a charitable commemoration of Her Majesty's most glorious reign. When this new asylum is ready for the reception of patients he trusts the governors may be able through legislative action to convert the Purdysburn manor house into an asylum for the reception of private patients of the middle and lower classes. The necessity for such an institution will be at once apparent, he says, when the large sums annually diverted from this country for the maintenance elsewhere of the wealthier classes of the insane are considered, while there is a very large number of private patients of the lower middle class whose friends cannot afford to pay a rate of board above, or much above, the average cost of maintenance of pauper patients, yet who are unwilling to submit to the stigma of pauperism in order to obtain asylum treatment for them. The provision of accommodation for this class in an institution detached from, but under the same management as, the district asylum would, in the inspector's opinion, meet a most important and charitable want.

The Battle of the Clubs at Cork.

Applications have been received on behalf of some forty members of two benefit societies which at the time of the rupture refused to accept the proposals of the medical profession to be allowed to have the ministrations of their old medical officer instead of being compelled to employ the imported newcomer. The forty members will accept the rules and pay for attendance at the following rates: 10*s.* for medical attendance and 5*s.* for medicine for self and family yearly. The incomes of all are under two pounds weekly. At a large meeting of the medical profession convened on Monday evening last the applications were granted subject to the stipulation that none be admitted except those who were members of the societies at the time of the promulgation of the rules. It is understood that similar applications in behalf of other medical men and their late club patients will be favourably entertained by the profession. In fact, it is clear

Hosted by Google

that in Cork those members of the community who have wits to see where their real benefit lies are determined to be just to their medical men and to obtain proper medical treatment free from the tyranny of self-interested officials.

Past Medical Students' Union.

A society for past students of the Catholic University has just been constituted. Its chief objects will be to bring together the students at an annual meeting and dinner and generally to assert their claims and defend their interests, especially in connexion with impending legislation. The following are the officers for 1897:—President: Mr. Laffan. Vice-Presidents: Mr. Dodd (Killorglin), and Mr. Duigenan (Edenderry). Chairman of Council: Mr. Kenny (Tallow). Secretary: Mr. Hourigan (Freshford). Council: Mr. J. J. Duigenan, Mr. P. S. Duigenan, Mr. O'Bierne, Mr. Clarke, Mr. M'Namara, Mr. Dodd, Mr. Sheedy, Mr. T. J. Daly, Mr. Kerrigan, Dr. Boyd, Mr. Kenny, Mr. Kilbride, Mr. Keating, Mr. Heffernan, Mr. Meehan, Mr. Furlong, Mr. Mr. M'Feely, Mr. O'Dwyer, and Mr. Laffan. Every past student, it is hoped, will join, and all communications should be addressed to the Secretary or President.

The Presidency of Queen's College, Cork.

The not unexpected retirement of Mr. Slattery from the presidency of the Cork Queen's College is now officially announced and three candidates are named as being in the field for the vacant appointment:—Sir Rowland Blennerhassett, Inspector of Reformatories and Industrial Schools in Ireland; Professor Corby, Professor of Midwifery in the College; and Mr. Starkie, of Trinity College, Dublin. The Lord-Lieutenant's choice is awaited with much interest by the general public and especially by the numerous medical graduates. It is believed the appointment will be made at an early date, probably at any moment during the coming three weeks, and as three-fourths of the students at the college are medical there is no doubt as to upon whom they hope the choice will fall.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Improvement in Diphtheria Antitoxin Serum.

PROFESSOR BEHRING announces in the *Fortschritte der Medicin* that he has succeeded in improving the diphtheria serum so that any obnoxious influence will henceforth be entirely avoided. The undesirable symptoms observed sometimes, such as exanthems, swelling of the joints, albuminuria, &c., are, in Professor Behring's opinion, due partly to the diphtheritic process itself and partly to accessory products which are present in the serum, pure antitoxin being a definite substance which only acts against the virus of diphtheria and otherwise has no influence on the organism. Professor Behring has not been able either to remove these products from the serum or to prevent their formation; but the strength of the serum, reckoned in antitoxin units, has been increased so much that only a small quantity is required and the unpleasant symptoms referred to are not now produced. This extra potent serum is sold by the Hoechst factory as a dry preparation, which, before being administered, must be dissolved in water. It is very soluble and may be kept for any length of time. It does not contain carbolic acid or any other antiseptic compound, but is simply preserved in hermetically closed bottles. The strength of one gramme is 5000 normal units. Professor Behring points out that the new antitoxin is especially valuable for immunising purposes; the immunity obtained by its administration lasts about four weeks. He hopes that the small number of medical men who are still opposed to the antitoxin treatment will now be persuaded of its efficacy and safety.

An Epidemic of Parotitis.

According to a communication of Dr. Marcuse in the *Deutsche Medicinische Wochenschrift*, an epidemic of parotitis has recently broken out in the northern districts of Berlin. In certain streets there is scarcely any house without patients. The illness rarely attacks adults, but is exceedingly prevalent among children, so that in some schools more than one-third of the pupils are prohibited from attending. The disease is of a mild character, fever lasting only for one or two days. The children seem to catch it at school, the incubation period is about a fortnight, and as a rule the patients recover within a week. In some instances, however, the swollen gland suppurates and high fever and other grave symptoms become developed so that surgical aid is necessary. Acute Bright's disease was also observed sometimes. Dr. Marcuse recommends a collective investigation for the purpose of inquiring into the causes of this epidemic.

University Fees.

In Germany a university student has to pay a fee each half-year for every lecture he attends, and this money becomes the property of the individual teacher. Under this system the professors who lecture on subjects required for examinations sometimes find their appointments very profitable, whilst those who lecture on matters of minor interest are placed at a great disadvantage. It is true that, in addition to the students' fees, the ordinary professors receive a fixed salary from the Treasury, but this salary is by no means adequate to the recipient's position in society, and the great majority of extraordinary professors and *privat-docents* do not get any remuneration from the Government. In order to redress this inequality the Government proposes to introduce a Bill providing that lecture fees exceeding 4000 marks (£200) in Berlin University and 2000 marks (£100) in the provincial universities shall be divided between the lecturer and the treasury. If, for instance, the fees paid by the students of a Berlin professor amount to 16,000 marks he would get only 10,000 marks and the remainder would be claimed by the treasury. The fund thus obtained will be used to increase the remuneration of the teaching staff of the university. The announcement of this contemplated innovation has with good reason caused a sensation among the members of the universities. They point out that the new measures will induce the members to raise the fees, and that the expense of university education, which in Germany is higher than in many other countries, will thereby be increased. The Bill would also restrict the liberty and freedom of action at present possessed by the universities and place them in a position of dependence on the Government. Although it is intended that the new regulations shall only come into operation gradually as new appointments are made, and shall not be applicable to the professors who already occupy chairs, the effect has been to cause so much uneasiness in university circles that the Government may possibly abandon the proposal.

The Medical Directory.

Börner's medical directory, edited by Dr. Julius Schwalbe, appeared last week. It shows that there are now 24,000 medical practitioners in Germany, the number having been 23,099 in 1896 and 16,292 in 1886. This means an increase of 47·2 per cent. There are 14,351 registered medical men in the Kingdom of Prussia, 2643 in Bavaria, 1766 in Saxony, 934 in Baden, 800 in Würtemberg, and 722 in Alsace-Lorraine, the remainder being in the smaller states of the confederation. Of the Prussian provinces the Rhenish province has the greatest number of practitioners—2208; the smallest number being in Western Prussia—449. There were 2077 medical men resident in Berlin at the end of last year, 523 in Munich, 487 in Hamburg, 447 in Breslau, 368 in Leipzig, 354 in Dresden, 292 in Frankfort, 257 in Cologne, 225 in Hanover, 212 in Charlottenburg (a suburb of Berlin), and 179 in Strassburg. The average number of practitioners is 4·59 for each 10,000 inhabitants, but this proportion varies very much according to the locality. In Berlin there are 12·38 practitioners for each 10,000 of the population, but the corresponding ratio is only 2·73 in the province of Posen. Compared with the census of 1890 the general population has increased 5·7 per cent., but the medical profession has increased 22·5 per cent. The number of licensed pharmacies was 5201; there were 5144 in 1895 and 4712 in 1886. Berlin has 152 licensed and controlled pharmacies; these figures, however, do not include the numerous class of druggists who are unlicensed, but nevertheless dispense medicine in defiance of the law, and thus do as much harm to the licensed pharmacists as the unqualified practitioners do to the regular medical men. The directory shows also an increase of dentists. There are now 1154 dentists with legal diplomas, the number having

Hosted by Google

been 1071 in 1895 and only 514 in 1886. The number appears somewhat small, but it must be remembered that dentists suffer very much from the competition of unqualified persons. The directory has a list of 3301 hospitals, including under this head the large municipal and University hospitals of Hamburg and Berlin, as well as small village infirmaries, private asylums, and special institutions of every kind. The total number of beds is 193,869. In Berlin there are 84 hospitals with 9000 beds, and in Hamburg there are 38 hospitals with 7000 beds.

Jan. 12th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Latest Views on Phthisis.

THE Associazione Medica Lombarda, as THE LANCET from time to time has shown, is eminent among her Italian sisters for work not more independent than sound, and the "full-dress discussion" the other evening, in which her leading members took part, on Phthisis, its Primary and Secondary Causes, was quite equal to her best traditions. Fifteen years ago phthisis was accepted by most pathologists as co-extensive with tuberculosis. It was an infective disease determined by the action exerted on various organs by the bacillus of Koch. The objection that it could be infective and at the same time hereditary was met by the explanation that not phthisis *per se* but the predisposition to phthisis was hereditary. The children of phthisical parents were thus particularly vulnerable in presence of the bacillus, a neglected "cold" or a slight influenza sufficing to invite the infection. The infective power of the bacillus was, indeed, the most formidable factor in the disease. No one was safe. Laboratory research showed the diffusion of the bacillus to be well-nigh limitless. Not only the air, but the food and drink, nay, the house furniture, the benches of schools, the compartments of railway carriages, the books of library shelves, and banknotes, all were potential or actual transmitters of the dreaded germ. 15 per cent. of the living harboured it; in the dead it was found in the ratio of 30 per cent. Panic at its ubiquity inspired the search for specifics against it. In spite, however, of antiseptic solutions, parasiticidal injections, and immunising serums innumerable the bacillus refused to yield, cropping up mercilessly in the sputum, to confirm what used to be ridiculed as an Italian superstition—viz., the danger of living near, or succeeding to, people given to coughing and clearing the throat. Of late years, however, the panic has died down. Phthisis is acknowledged to be eminently curable. Under sound hygiene pulmonary tuberculosis is daily being arrested. Surgical intervention often suffices to cure a peritoneal phthisis. The sputum is seen to be dangerous only in a state of perfect desiccation. Even the breath of the phthisical may be respired with impunity. The bacillus of Koch, though still a power, is no longer supreme according to many pathologists. According to others there are concomitant bacilli even more dangerous, to which that of Koch is simply the "crossing-sweeper" facilitating their entrance. Thus, these observers explain the fact that in all the more pronounced cases of phthisis there are found other bacilli; while those cases in which the bacillus of Koch is alone detected are generally mild and run an easily tractable course. The hectic fever, symptomatic of the graver forms of phthisis, is accounted for by these concomitant bacilli only. Yet another group of pathological assailants the bacillus of Koch has to confront. These would assign it a simply accidental *rôle*—appearing in local manifestations merely, manifestations well defined and eminently curable. The disease caused by it is nothing more than a scrofulosis, in which the glands, the skin, the cartilages, and the bones disclose its invasion, with a reaction for the most part favourable. The bacillus, for example, may lie hid in some viscus of a healthy subject whose resisting power by a blow or a wound is temporarily impaired, but which soon rights itself, to the expulsion of the intruder. Phthisis according to the consensus of debaters led by Dr. Gatti at the Associazione Medica Lombarda, being not due to the bacillus of Koch, being neither infective nor contagious, resolves itself into what it appeared to be to the former generation—a disease of nutrition, a perversion of hygienic conditions due to causes economic, social, and others having their roots in our *modus vivendi*. The primary, the essential factor in the evolution of the phthisical state is degeneration, organic decay, while the intervention of the bacillus of Koch represents only "un accidente terminale," a modification of a process already determined. In certain subjects, honeycombed by insufficient alimentation, tuberculosis is but an anticipation of the decomposition ensuing after interment. As, indeed, Virchow and Hansemann have shown, there are phthisical patients in whom the bacillus of Koch is "conspicuous by its absence," while there are maladies—diabetes, for example—in which tuberculosis is a complication almost invariably present. We return, then, to the pathology, the prophylaxis, and the therapeutics of our fathers—such, at least, is the outcome of the memorable discussion by the Milanese pathologists and consultants the other evening—and relegate to the first line among the causes and the cure of phthisis those factors and agents which have been temporarily pushed back into the second—factors represented by a violated hygiene, and agents recruited from the resources by which that hygiene is vindicated and restored.

Pellagra.

The "Response to Treatment" has always been valued as an aid to diagnosis, and if any doubt existed as to the nature or presence of pellagra it must have disappeared before the measures taken to combat it of late years. The Ministry of Agriculture has seen to the provision of bakeries, "essiccatoi" (drying apparatus), cheap kitchens, and better house accommodation is the pellagra-visited neighbourhood; and also has erected "pellagrosari," or places for the treatment of "pellagrosi" after the disease had acquired a foothold. For the latter purpose there were spent in 1892-93 5300 lire (£212); in 1893-94 as much as 20,050 lire (£802); and in 1894-95 the still larger sum of 33,922 lire 84 centesimi (about £556 18*s.* above the latter sum). The reports which the Ministero has received from the said neighbourhoods are unanimous in announcing a decrease in the malady consequent on the provisions referred to—all except Perugia, which (for certain local reasons) registers an augmentation. Improved health conditions, notably in the direction of wholesome alimentation, are thus demonstrated to be the one thing needful in preventing pellagra, and so the Ministero contemplates reinforcing itself by a further instalment of the same measures which have already proved their own efficacy and the wisdom of their promoters.

Jan. 9th.

Obituary.

SAMUEL W. BROADBENT, M.R.C.S. ENG.

A STRIKING personality has passed away by the death of Samuel Winn Broadbent, at his residence, Easington, County Durham, on the 29th ult. No man was better known or more respected in the county, and he was the veritable *doyen* of the country practitioners of the North-East of England. Born seventy-eight years ago in India, where his father was a Wesleyan missionary, he came to England at an early age, and after a sound preliminary education he was apprenticed to the late Mr. Henzell, surgeon, of Percy-street, Newcastle-on-Tyne. Later he attended lectures at the Newcastle School of Medicine and subsequently at the Middlesex Hospital, obtaining the M.R.C.S. Eng. in 1850. Of an adventurous spirit, he for some years acted as surgeon to a whaling fleet, and after a few years in practice in various parts of the county of Durham he was appointed surgeon to the collieries of the South Hetton Coal Company, which responsible post he held for over forty years, and when a few years ago he felt that the time had come for him to retire from his onerous duties the Company generously made him a retiring allowance in recognition of his past services. He then went to live at Easington and continued to act as medical officer to the Easington workhouse, an

Hosted by Google

appointment which he held from the time it was built until he died. He joined the Volunteers shortly after they were formed, and by resigning only a few months before the V.D. was created missed that distinction, as he had very nearly completed his twenty years' service. He took an active and most energetic interest in the local medical societies and was an ex-president of the North of England branch of the British Medical Association and also of the Northumberland and Durham Medical Society and had been one of the most prominent members of the executive of these societies for many years. He was very regular in his attendance at the annual meetings of the British Medical Association, having been present on thirty-three occasions. He was an occasional contributor to the Transactions of the Northumberland and Durham Medical Society and frequently took part in its debates. Mr. Broadbent was a most hospitable man, a genial companion, and an excellent *raconteur*. The funeral, which took place on New Year's Day, was attended by the whole neighbourhood.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Josef von Gerlach, who may be called the Nestor of German anatomists. After taking his degree at Würzburg he visited London and other medical centres and settled down to private practice in Mayence. He found time and opportunity, however, of continuing his scientific work and published his well-known "Manual of General and Special Histology." He was subsequently appointed to the chair of Anatomy in Erlangen, which at that time implied his teaching pathological anatomy and physiology. He was relieved of the one by the appointment of Professor Zenker and of the other by that of Professor Rosenthal. His microscopical work has been productive of advance in science, especially in the staining of specimens and in the application of photography to the microscope.—Dr. Carl Heitzmann, after taking his degree in Vienna, settled in practice in New York, where he established a laboratory for medical microscopy and published an anatomical atlas of plates. He died in Rome after a protracted illness.—Dr. Asper Stadfeld, Professor of Gynæcology in Copenhagen.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—The following candidates at the Primary Examination have passed in the under-mentioned subjects:—

PART I.

Biology.—A. E. Brown, Royal Free Hospital; R. Burnham, Charing-cross Hospital; T. M. Burton, A. M. Dodd, E. A. Dunn, A. E. Gilford, K. Heanley, H. M. O. Jones, D. E. Lockwood, L. S. Molony, F. M. Payne, and C. E. Sholl, Royal Free Hospital; and A. Turner, City School of Chemistry.

Materia Medica and Pharmacy—A. L. Bartram, Cambridge and Westminster Hospital; R. S. Elvins, Birmingham; T. B. Haig, St. Bartholomew's Hospital; H. Towers, Leeds; and M. E. Unwin, Royal Free Hospital.

PART II.

Anatomy and Physiology.—A. G. C. Davies and F. J. Featherstone, Guy's Hospital; C. S. Hawes, St. Bartholomew's Hospital; J. E. Howroyd, Leeds; E. Hudson, St. Thomas's Hospital; A. M. Macintosh, St. Mary's Hospital; C. B. Sells, Guy's Hospital; G. M. Smith, St. Thomas's Hospital; N. Walmisley, St. Bartholomew's Hospital; A. J. Watson, St. Mary's Hospital; and T. R. Wilshaw, Birmingham.

Anatomy.—S. K. Cama, Bombay; S. F. Cheesman, Charing-cross Hospital; A. Croneen, Guy's Hospital; G. A. Crowe, London Hospital; G. R. Lucas, Edinburgh and St. Bartholomew's Hospital; T. Morgan, Guy's Hospital; G. Steel, Cambridge; D. L. Thomas, Birmingham; and H. C. Woodward, Cambridge.

Physiology.—W. Alcock, Sheffield; E. C. W. Beasley, St. Mary's Hospital; J. C. S. Dunn, St. Bartholomew's Hospital; F. J. F. Jones, Guy's Hospital; S. Page, Birmingham; and T. M. Talbot, St. Bartholomew's Hospital.

FOOTBALL CASUALTIES.—While playing recently for the Brighton Association in a match against the Portsmouth team a player fractured his right fibula.—During a match on the 2nd inst. between the Old Windsor Club and a team of the *Windsor Chronicle* employés on the "Duke of Edinburgh" ground the Old Windsor back sustained severe injuries "below the ribs and in the abdomen" and was conveyed to the infirmary. He subsequently returned home and is now in a serious condition.—On Saturday last, in a match, Todmorden against Hebden Bridge, on the ground of the latter, a Todmorden player fractured his clavicle.—On the same day, at Lincoln, during a match, the Lincoln City against the Grimsby Town team, the City outside left fractured his ankle.

MR. EDWIN P. GUTTRIDGE, the medical officer of health, has been awarded ten guineas by the Maldon Town Council as an honorarium for extra work in superintending and managing during five months the Isolation Hospital.

LITERARY INTELLIGENCE.—Messrs. Baillière, Tindall, and Cox announce as ready for publication the seventh edition of Dr. Macnaughton Jones's "Diseases of Women and Uterine Therapeutics," which has been re-written and brought up to date; the fifth edition of Professor Delafield's well-known text-book of "Pathological Anatomy and Histology"; the third edition of Dr. Bosworth's "Treatise on Diseases of the Nose and Throat"; the second edition of Mr. Lennox Browne's "Diphtheria and its Associates," the first edition having been out of print for some months; and a translation by Dr. F. Lucas Benham of Professor Brouardel's classic work on "Death and Sudden Death." The same firm has also in the press a third edition of Dr. Ball's "Diseases of the Nose and Pharynx," and a new work by Mr. Mayo Collier on "Chronic Nasal Obstruction."

DIPHTHERIA IN LONDON.—The current registration year has opened in a very unpropitious manner in so far as fatal diphtheria in London is concerned. In the week ended with last Saturday there were registered in the administrative county 71 deaths from the disease, a number as many as 30 in excess of the corrected average for the first week of the ten years 1887–96. The totals for the three closing weeks of last year were severally 58, 38, and 49. Of the 71 deaths there were 68 in young persons aged from one year to twenty years; and the sanitary districts credited with more than one death were numerous, including Islington with 6, Shoreditch, Poplar, Wandsworth, and Camberwell each with 5, St. Pancras, Mile End Old Town, Bermondsey, and Lambeth, each with 4, and St. Marylebone, Whitechapel, Newington, and Woolwich, each with 3 deaths. There were 104 cases of diphtheria admitted to hospital last week, as compared with 125, 129, and 115 in the three weeks preceding, and there were 867 patients still under treatment on Saturday last in the London hospitals suffering from the malady. In addition to the deaths registered in the county of London there were no fewer than 14 last week in the outer ring of the metropolis, of which 3 were in persons belonging to the West Ham and 6 to the Edmonton registration districts. Thus, there were in one week 85 deaths referred to diphtheria in Greater London. The significance of these figures is seen when it is pointed out that in the whole of the thirty-three great towns of the Registrar-General there were only 103 deaths registered from the disease last week, and of the 30 outside Greater London 7 were in Birmingham, 4 in Leicester, and 3 each in Liverpool, Birkenhead, and Leeds.

THE CRAIG COLONY FOR EPILEPTICS.—The third annual report of this American institution, which has just been published, is a very interesting and useful document. The colony has been founded by the State of New York, and funds were available for purchasing a suitable area of land and for equipping it with the necessary appliances for a farm colony. Nearly 150 colonists have been admitted, all of whom take part in the work of the colony. It is not stated in the report to what extent and at what expense this has to be supplemented by skilled persons to direct the labour. As at the Chalfont Colony in this country the improvement in the mental and physical health of the colonists has been very pronounced, while the actual curative effect on the epileptic attacks has been less marked. Three patients had to be discharged on account of insanity. The report is supplemented by interesting analytical tables, showing the supposed cause of the fits in each case, the nature of the aura, the time of day at which fits occur most frequently, and so on. A full and very varied dietary for one week is given, which will be found useful by those who have to advise epileptics. Fresh vegetable food enters largely into the list; meat is allowed once a day. It is satisfactory to learn that the raising of garden produce, the tending of hens and other animals have been so successful that it is believed the colony will

Hosted by Google

soon pay its own expenses. Of course this has only been possible by the wise arrangement of spending enough money at the outset to equip the institution thoroughly. The example of the New York State might well be copied by our Poor-law authorities and the epileptic colonies now in existence be taken in hand and generously supported. Excellent work is being done at Chalfont and other institutions, but for want of funds comparatively few colonists can yet be accommodated, and much outlay is still required before suitable employment can be found for all in summer and winter.

FREEMASONRY: THE RAHERE LODGE.—A regular meeting of the Rahere Lodge was held at Frascati's Restaurant, Oxford-street, on Thursday, Jan. 12th, 1897, W. Bro. Alfred Cooper, F.R.C.S. Eng., the W.M., in the chair. Dr. Lovell Drage and Dr. Eddowes were elected joining members of the Lodge; Bros. Owen Lankester, Horton-Smith, Gow, Laming Evans, Sloane, Perran, and McLean were admitted to the second degree, and Bros. Keetley and Newton to the third degree; and Dr. G. V. Worthington was initiated into Freemasonry. Bro. Reece, the treasurer, reported that the condition of the Lodge funds had enabled him to invest £300 in India Three per Cent. Stock. Forty-nine brethren afterwards dined together Bro. Sir Reginald Hanson, Bart., M.P., Bro. Col. Cooke, Bro. Anderson Bates of Grimsby, and Bro. J. E. Lane being amongst the guests.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index for the second volume of 1896 was given in the issue of Dec. 26th last. The practice of supplying loose copies has been discontinued, the Index having been placed in the centre of the journal, whence it can easily be detached, and placed either at the beginning or at the end of the volume.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1896 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.* (Local bookbinders will charge about 1*s.* for binding the numbers in these cases.)

To be obtained on application to the Manager, accompanied by remittance.

"THE PREVENTION OF THREAD WORMS: A QUERY."

To the Editors of THE LANCET.

SIRS,—Provided the little girl has no specific ailment rendering the constitution a favourable one for the thriving of parasites, and supposing her to be only suffering from the general debility usually associated with the existence of thread-worms, your correspondent "Persevere" could scarcely do better than administer such a tonic as syrupus ferri phosphatis compositus (Parrish) for some weeks, and give injections of infusum quassiæ, or common salt solution, three times a week as long as any signs of presence of the worms remain, and perhaps once or twice afterwards. I am, Sirs, yours faithfully,

Buckhurst Hill, Jan. 9th, 1897. HAYDN BROWN, L.R.C.P., &c., Edin.

THE POLICE AND MEDICAL AID.

To the Editors of THE LANCET.

SIRS.—On the 20th ult., coming upon a crowd in Kensington High-street I went as usual to see if medical assistance was needed. I found a ring of six or eight constables proffering some liquid to a man lying on the pavement and looking very ill. Receiving from a constable a merely negative reply to my query as to whether the invalid had been already seen by a medical man, I proffered my services but was brusquely informed "We do not call you in." In the interests of the public I at once reported the matter to the local superintendent, asking him if, in such a case, the police were justified in refusing gratuitous medical assistance on their own responsibility. I have now received a reply and enclose it with this for your editorial comments.

I am, Sirs, yours faithfully,

Jan. 8th, 1897. ROBERT J. COLENSO.

"New Scotland Yard, 6th Jan. 1897.

"SIR,—With reference to your letter of the 20th ultimo I am directed by the Commissioner of Police of the Metropolis to acquaint you that, in cases of emergency it would be the duty of the police to accept the services of any medical man who was kind enough to proffer them. In the case in question, however, there was no such emergency, and, moreover, the divisional surgeon had been sent for and his arrival was momentarily expected. On occasions such as these the police must necessarily act on their own responsibility, and, while acting in the interests of the public, must at the same time, so far as possible, avoid the expense incurred by accepting the services of two medical men in one case.

"I am, at the same time, to add that the Commissioner fully appreciates the kindly feeling which prompted you to offer your services, and to express his regret that the officer in the case was not more explicit in explaining that he was not able to accept your aid because the divisional surgeon had been already sent for.

"I am, Sir, your obedient servant,

"C. L. BATHURST, Chief Clerk."

*** The policemen incurred a grave responsibility in deciding to dispense with the proffered medical services. They should have explained that the divisional surgeon was expected and that the case must be considered as under his charge, and then have availed themselves of the aid at hand. It is not always a good thing "to proffer liquid to a man lying on the pavement," even if the treatment suggests itself to the collective medical wisdom of six or eight policemen. If by any chance, under such circumstances, the wrong sort of "liquid" were administered to the wrong sort of case and a coroner's inquest should result, in what sort of a position would the policemen stand when it was given in evidence that an opportunity of obtaining medical advice had been brusquely ignored?—ED. L.

J. J. H. (Lancs).—The charge made was not in conformity with professional usage, but our correspondent will remember, firstly, that there was no legal obligation upon the medical man to attend the young lady for nothing, and, secondly, that we are expressing an opinion upon the statement of one side only.

"MALT NUTRINE."

THE Anheuser-Busch Brewing Association of New York writes as follows in reference to an analytical notice of this preparation which appeared in THE LANCET of Nov. 14th: "While we have no possible reason to doubt that your examination of 'Malt Nutrine' was conducted with your usual care and precision there appears to us to have been a slight error (probably clerical or typographical) in regard to the reported proportion of alcohol." In spite of the results being higher, as is pointed out, than those obtained by other journals and authorities we find we committed no error, clerical, typographical, or otherwise. On repeating the analysis the result was precisely the same. The sample thus tested belonged to the consignment which was submitted to us at the first.

S. E.—It is our belief that it has been held that such notices should be stamped, but we have been unable to find the decision in a similar case.

"RONTOGRAPHY"?

To the Editors of THE LANCET.

SIRS,—Not only the medical, but the whole scientific world is at present much exercised over Professor Roentgen's great discovery. It seems that he, with that modesty so characteristic of great men, has called the rays the x rays; but no term quite agreed upon generally has been found to describe the images or pictures. Sometimes they are called shadowgraphs—a hybrid name—sometimes skiagraphs, and not infrequently photographs. It has occurred to me that it might be a gain to exact nomenclature, and a worthy tribute to the inventor, if they were called Rontographs, and the process Rontography. The verb would also, of course, be Rontograph. I leave out the mark to show that the vowel in the first syllable is modified, as this sound is more easy of pronunciation to an English ear. I leave this consideration for the opinion of your numerous readers.

I am, Sirs, yours faithfully,

Elgin, N.B., Jan. 11th, 1897. TERMINOLOGY.

"THE UNQUALIFIED ASSISTANT."

To the Editors of THE LANCET.

SIRS,—Now that the election of direct representatives to the General Medical Council is a thing of the past let me ask, What is the use of the Council? It certainly affords the representatives a trip to headquarters twice a year but that is about all. Regarding the question of the unqualified assistant, the Council holds a very peculiar position. It does not recognise such an assistant, but all the same he flourishes. The General Medical Council strikes with one hand and pats with the other. In my district there are four qualified medical practitioners; one of these employs two unqualified assistants who have been here for nearly twenty years. One of the assistants lives near the surgery, while the second conducts a branch practice nearly three miles distant. This is in defiance of the Council, which knows of such a practice but will not take up the case without a local complaint. Surely this is red tapeism with a vengeance. Death and other certificates have been granted by these unqualified men and, what is worse, these papers were accepted by the local registrar.

I am, Sirs, yours truly,

Jan. 10th, 1897. REGISTERED.

Enquirer.—It seems to us probable that the General Medical Council would regard the relation between principal and assistant as one of "covering."

A NEW TERROR.

AT a recent meeting of one of the medical societies a gynæcologist related a story which at once shows commendable forethought on the part of the young woman and the dangers, other than physical or physiological, which may be the price paid for "irregular unions." A single woman, aged twenty-two years, had some two years previously given birth to a child. Of late she had ceased to menstruate, and as her abdomen began to enlarge she thought she was again pregnant, so she accordingly took the precaution of obtaining from the supposed father a weekly allowance. Her next step was to consult the gynæcologist in question, who, finding her symptoms to be due to an ovarian cyst, removed this. We presume that when the putative father finds that the lady, like the widow in "The School for Scandal," has "recovered her shape in a surprising manner," that the weekly allowance will cease, but this is possibly the first case on record where an ovarian cyst has been a source of income to the possessor.

M. D.—The evidence given before the Royal Commission on Vaccination is comprised within five volumes—viz.: First Report, dated August 12th, 1889, price 2*s.* 3*d.*; Second Report, dated May 29th, 1890, price 7*s.* 4*d.*; Third Report, dated August 7th, 1890, price 7*s.* 6*d.*; Fourth Report, dated July 28th, 1891, price 6*s.* 7*d.* The Sixth Report is not yet issued. Those published can be obtained from Messrs. Eyre and Spottiswoode. The Commission held its first sitting in June 1889, and in April, 1892, issued an interim report (Fifth Report, price 1*d.*) dealing with the question of cumulative penalties. Its final report (with Appendices I. and II. and the dissent of Dr. Collins and Mr. Picton, price 1*s.* 10*d.*) was issued in August, 1896. There still remains to be issued as separate volumes Appendices III. to IX. to the final report, comprising reports upon small-pox outbreaks, undertaken on behalf of the Commission, and reports upon vaccinal injuries. We believe that most, if not all, of the outstanding reports will be issued after the meeting of Parliament.

"THE LAWRENCE PROCESS OF SOFTENING AND STERILISING WATER."

THE apparatus described in the article which appeared in our issue two weeks ago under the above heading is made by The Lawrence Water Steriliser Co., Norland Yard Works, Uxbridge-road, W.

M. O. H. has omitted to send us his name and address.

During the week marked copies of the following newspapers have been received:—*Wolverhampton Chronicle, Mid-Surrey Gazette, South-Western Star, Worcester Echo, Daily Mail, Dunstable Borough Gazette, Jackson's Oxford Journal, Times of Ceylon, Pullen's Kent Argus, Newcastle Journal, Brighton Argus, Daily Chronicle, Times of India, Dundee Courier, Hastings News, Birmingham Gazette, Pioneer Mail, Builder, Cambrian, Rochester Journal, Liverpool Daily Post, Tunbridge Telegraph, Architect, Norfolk Chronicle, Thanet Advertiser, Berkshire Chronicle, Bristol Mercury, East Anglian Daily Times, Kentish Mercury, Yorkshire Post, Hull News, Sheffield Telegraph, Manchester Guardian, Leeds Mercury, Scotsman, Leicester Post, Bradford Observer, Sussex Daily News, Auckland Times, Woking Mail, Windsor Express, Lincolnshire Echo, Sanitary Record, Egyptian Gazette, Reading Mercury, Weekly Free Press and Aberdeen Herald, Local Government Chronicle, Hertfordshire Mercury, Lincolnshire Chronicle, City Press, Le Courrier de la Presse, Manchester Courier, Mining Journal, Local Government Journal, Surrey Advertiser, Derbyshire Courier, South Africa, Macclesfield Courier, Southend Standard, Kelso Mail, Dereham Standard, Henley Standard, Salisbury Journal, Burnley Express, Inverness Courier, West Middlesex Herald, Daily Argus, Crewe and Nantwich Advertiser, Bucks Standard, Bristol Times and Mirror, &c.*

Reliable Products of Scientific Pharmacy.

VOLUMETRIC TEST "SOLOIDS."

INVESTIGATIONS have, for some time past, been carried on in our laboratories with a view to issuing a complete series of Test "Soloids" for the purposes of volumetric estimation. These experiments have given extremely successful results, and have added further testimony to the absolute accuracy and reliability of "Tabloids" and "Soloids" of compressed drugs. We are now issuing the following Test "Soloids" for water analysis:—

Silver Nitrate "Soloids," each corresponding to 2 milligrammes of chlorine.
Potassium Chromate "Soloids."
Sodium Acid Sulphate "Soloids."
Potassium Iodide and Starch "Soloids."
Zinc Dust "Soloids."
Soap "Soloids," each corresponding to 5 milligrammes of Calcium Carbonate.
Potassium Ferrocyanide "Soloids."
Potassium Permanganate "Soloids," each corresponding to 10 milligrammes of oxygen.

These are put up in tubes, each containing 25 and 100 "Soloids," and will appeal especially to Medical Officers of Health, as their portability permits of analyses of water being conducted at the source of supply.

Still more important groups of Volumetric Test "Soloids" will shortly be issued, as we have in the course of active preparation "Soloids" of all chemicals used in volumetric analysis.

RED GUM "TABLOIDS" (B., W. & CO.).

Red Gum, an exudation from the Australian *Eucalyptus Rostrata*, is a mild styptic and antiseptic, and an excellent local and general astringent. When a Red Gum "Tabloid" is allowed to dissolve in the mouth, the continuous action of the drug on the throat is fully secured. Great care has been exercised so to adjust the relative proportions of the ingredients that the full therapeutic effect of the drug may be obtained without offending the palate or affecting the appetite.

Supplied in boxes of 30 and bottles of 100 "Tabloids," at 6d. and 1s. each.

COMPOUND PHENACETIN "TABLOIDS" (B., W. & CO.).

"The investigations of the Therapeutic Committee of the British Medical Association conclusively proved that phenacetin is one of the safest antipyretics, and experienced physicians find that in small doses it succeeds when others fail. But even small doses sometimes depress the heart greatly. Hence the introduction by Messrs. Burroughs, Wellcome & Co., of a compound phenacetin "Tabloid" containing 4 grains of phenacetin and 1 grain of caffeine is appropriate."—THE CHEMIST AND DRUGGIST, January 9th, 1897.

Compound Phenacetin "Tabloids" are supplied in bottles of 25 and 100, at 10d. and 2s. 3d. per bottle.

CASCARA SAGRADA & BELLADONNA "TABLOIDS" (B., W. & CO.).

A valuable combination containing intestinal stimulant, tonic and laxative ingredients, the formula being:—

Cascara Sagrada Extract	2 gr.
Nux Vomica Extract	¼ gr.
Belladonna Extract	⅓ gr.
Capsicine	⅛ gr.

The MEDICAL PRESS, Dec. 16th, says: "The 'tabloids' being sugar-coated constitute a very agreeable form of exhibiting the combination."

Compound Cascara Sagrada and Belladonna "Tabloids" are supplied in bottles of 25 and 100 at 9d. and 1s. 6d. per bottle.

COMPOUND BROMIDE "TABLOIDS" (B., W. & CO.).

Each "Tabloid" contains—

Strontium Bromide...	2 gr.
Sodium Bromide	2 gr.
Ammonium Bromide	1 gr.
Sodium Arseniate	1/10 gr.

In cases where the bromides have to be administered in large doses and regularly it is found that the salts of strontium, sodium and ammonium are less depressing than that of potassium, and that the combination of these three bromides, with a small dose of an arseniate, forms the best method of continuous bromide treatment. In the Compound Bromide "Tabloid" the dose of arseniate of sodium is such as to allow six "tabloids" (that is thirty grains of the combined bromides) to be given in one dose when necessary.

Compound Bromide "Tabloids" are supplied in bottles of 100 "tabloids" at 1s. 4d. per bottle.

EMOL-KELEET.

Since the favourable reports which marked the introduction of this preparation many appreciative opinions have been expressed both by physicians and by the professional press.

THE LANCET says:—On account of its remarkable velvety smoothness it should possess a unique value as a dusting powder in the treatment of cutaneous diseases, &c., and for allaying irritation. We have not examined a more unctuous earth."

BRAITHWAITE'S RETROSPECT OF MEDICINE says:—"Emol-Keleet is the most beautiful, impalpable, mineral powder with which we are acquainted, and promises to supersede all the older forms of dusting powders. We have made use of it for some time past in the treatment of eczema, especially in infants and young children, where dry and soothing agents are most desired, and have found it to be a most excellent application in such cases, while the readiness with which it can be used and its absolute freedom from all risks of decomposition, add largely to its value.

Emol-Keleet is supplied to the profession in boxes at 9d. each.

ARMOUR'S

GLYCERINE EXTRACT OF RED BONE MARROW.

THE LANCET, Sept. 22nd, 1894.—Dr. W. G. BIGGER reports a case of Leucocythæmia apparently cured by Bone Marrow.

The BRITISH MEDICAL JOURNAL, Feb. 16th, 1895, contains a report by Dr. BARRS of a case of Pernicious Anæmia treated by Arsenic, in which arsenical palsy had been induced, and the case was cured by the administration of Bone Marrow.

THE LANCET, Dec. 7th, 1895, reports cases in which, by the use of Red Bone Marrow, the rate of production of Red Blood Corpuscles showed an increase of more than a million per cubic millimetre in from four to nine weeks.

ARMOUR'S BEEF JUICE

Is prepared by *cold* expression from only finest selected material—of which **ARMOUR & COMPANY, Chicago,** have an almost unlimited supply. To the Medical Profession this appeals strongly on account of its high value in all cases where nourishment and stimulant are required. It can be administered diluted with milk or water, so forming a pleasant, refreshing beverage, with the greatest possible amount of nourishment at one draught.

The Juice, while retaining the rich beef flavour, also contains in perfect solution a good percentage of albuminoids. It also contains 33% to 35% of solid matter, consisting of Beef Extractives and mineral matter, the latter containing Soluble Phosphates, &c.

Packed in 2½-oz. Amber Flagons.

STOCKED BY LEADING WHOLESALE HOUSES.

It is respectfully requested that, when prescribing, "ARMOUR'S" may be indicated.

Valedictory Address
ON
ANTISEPTIC MIDWIFERY.

Delivered before the British Gynæcological Society on Jan. 14th, 1897,

BY CLEMENT GODSON, M.D. ABERD., M.R.C.P. LOND,
PRESIDENT OF THE SOCIETY, CONSULTING PHYSICIAN TO THE CITY OF LONDON LYING-IN HOSPITAL.

GENTLEMEN,—It has been customary at this meeting of the Society for the outgoing President to deliver a valedictory or farewell address, and the subject not infrequently taken has been a review of the work done by the Society during the past year. Your last two Presidents, Professor Savage and Mr. Jessett adopted this plan, and last January in my address—not a valedictory one, however, owing to your having paid me the compliment of electing me to occupy the chair for a second year—I followed their example. But now, in order not to make this appear an established custom, I am taking a different course. One of your former Presidents, Dr. Grigg, Physician to Queen Charlotte's Lying-in Hospital, at the end of his inaugural address, said "the lateness of the hour prevents my touching upon the question of the influence of antiseptics during parturition. I believe that it will be found that antiseptics have revolutionised the rules of obstetric practice." Another of your past Presidents, Dr. Bantock, quite recently writes[1]: "He asks me to explain the marvellous effects of the antiseptic method in midwifery practice; I say they are due to the adoption of the principle of cleanliness, and on the contrary side would call his attention to the large number of deaths due to poisoning by corrosive sublimate which medical literature affords." The opinions of your two past presidents are so at variance with one another, that I thought I could not do better than take up this subject for my address this evening, and give you some account of the City of London Lying-in Hospital, and the results to the patients, which have not yet been published except in the annual reports of the hospital, in order to corroborate the testimony given respecting the General Lying-in Hospital since corrosive sublimate was introduced there as an antiseptic by Sir John Williams and Dr. Champneys in May, 1884, who followed the example which had been set by Dr. Tarnier in the Maternity Hospital in Paris.

It was the publication of the admirable results obtained by the physicians at the General Lying-in Hospital that decided us to discard carbolic acid in favour of corrosive sublimate as our antiseptic, when the City of London Lying-in Hospital was re-opened on July 1st, 1886, after having been closed for a short period for thorough cleansing, as was the annual custom. The strength of the solution used was 1 in 1000 for the hands of the attendants, and 1 in 2000 for vaginal irrigation. I gave a full account of how it was employed in a lecture I delivered at the Midwives' Institute and Trained Nurses' Club on Oct. 14th, 1887, which was subsequently published and distributed among the midwives and nurses in pamphlet form; and, except in small details, it has been used in the same manner up to the present time, Dec. 31st, 1896, just ten and a half years, on 4608 women, without a suspicion of mercurial poisoning in one.[2] Therefore I think we may at once dismiss the idea of any risk of poisoning in the way in which it is now used, and should be used, and it will probably be found that what Dr. Bantock refers to relates to when intra-uterine injections were employed of a strength of 1 in 1000, or stronger, such as those reported by Dr. Dakin in a paper on Mercurialism in Lying-in Women undergoing Sublimate Irrigation, read at the meeting of the Obstetrical Society of London in December, 1886. Dr. Dakin brought the subject forward not with the view of advocating the discontinuance of its use, but to endeavour to elicit the best means of employing it with safety, for he says, "the results at the General Lying-in Hospital have been such as to make the physicians loth to dispense with it."

In an admirable address[3] by Dr. Cullingworth on "Puerperal Fever a Preventable Disease," he says: "Until the year 1877 this hospital [the General Lying-in Hospital] was scarcely ever free from puerperal fever, and the mortality, always high, occasionally became fearful. In 1838 of 71 women delivered 19 died; in 1861 14 died out of 195; and in 1877 9 out of 63. On several occasions the hospital had to be closed for long periods, and thousands of pounds were spent on the sanitary improvement of the building. In October, 1879, this institution, having been closed for two years, was re-opened, and has since been conducted on antiseptic principles, the details varying from time to time as increased knowledge and experience have dictated. Mark the result," and he gives the following table:—

Period.	Deliveries.	Deaths.	Average death-rate from all causes.
			Per cent.
1833 to 1860	5833	180	1 in $32\frac{1}{4}$ = 3·088
1861 to 1877	3773	64	1 ,, $58\frac{7}{8}$ = 1·696
1880 to 1887 — antiseptic period	2585	16	1 ,, $161\frac{1}{2}$ = 0·618

This last period of eight years takes in three varieties of antiseptics used, first carbolic acid, next permanganate of potash, and finally corrosive sublimate. Dr. Boxall, in a masterly paper read at the June and July, 1890, meetings of the Obstetrical Society, (which I recommend to the attention of you all) gives another period, from the time corrosive sublimate alone was used—May 1st, 1884, to June 30th, 1889, 2150 deliveries, 9 deaths, 1 in 239 = 0·418 per cent.—a much greater diminution in the death-rate.

I propose to contrast the results at the City of London Lying-in Hospital from the time that I became connected with it, in March, 1870, up to the end of April, 1886—a period of 16 years—with that commencing July 1st, 1886, when corrosive sublimate as the antiseptic came into use there, up to Dec. 31st, 1896—a period of $10\frac{1}{2}$ years,—and I think you will find that it thoroughly bears out what Dr. Cullingworth has said in his address and what Stadfelt of Copenhagen has expressed, his opinion being emphatically endorsed by Dr. Boxall in his paper to which I have referred,—"the belief that the hygiene of a maternity depends less upon its construction and its age than upon the hygienic principles upon which it is directed and upon the perseverance with which these principles are carried out in the daily practice." For you will learn that while structural alterations failed to improve the condition at the City of London Lying-in Hospital, hygienic principles and, markedly, the employment of corrosive sublimate produced an extraordinary change for the better.

I will say a few words about the hospital itself, and my connexion with it. The present building was erected in the City-road, at the corner of Old-street, in 1771, and was opened for the reception of patients on March 31st, 1773—so that it is 124 years old. There is not now, nor has there ever been, a house surgeon; the chief resident is termed matron and midwife. There is only one medical officer in charge, who resides in the neighbourhood and visits the hospital daily and whenever required. He is termed the surgeon-accoucheur. I took over the duties of this office in March, 1870, though I was not permanently appointed to fill it till the following July. There are two other medical officers, a consulting physician and a consulting surgeon. These are not complimentary honorary appointments as the term "consulting" often implies. The surgeon-accoucheur is expected to call to his aid the consulting physician whenever he is in difficulty in a delivery or in any case of serious illness, and he has the consulting surgeon to appeal to in any case that is surgical outside midwifery and gynæcology. Both these medical officers have a seat on the managing committee. I resigned my appointment of surgeon-accoucheur in 1871, and in 1872 was elected from among the governors a member of the committee of management, the meetings of which I attended as regularly as possible up to July, 1881, when Dr. Greenhalgh resigned his office of

[1] Medical Press and Circular, Nov. 18th, 1896.

[2] A vaginal douche of 1 in 2000 at a temperature of 115° is given immediately after the delivery of the placenta, and three similar douches subsequently at intervals of night and morning; then iodine douches are given instead of sublimate.

[3] Delivered at St. Thomas's Hospital, London, and published by J. & A. Churchill, 1888.

Hosted by Google

consulting physician, and I was appointed in his place; so that it will be seen that for nearly twenty-seven years I have taken an active part in the affairs of the hospital.

In 1870, when I took over the medical charge, the patients were dying in the proportion of 1 in 19—12 deaths occurring among the 227 women delivered—so that as soon as possible, seconded by Dr. Greenhalgh, I appealed to the committee to close the hospital. Its doors were shut on June 15th for three months in response to our entreaty. I immediately set to work to endeavour to discover the defects and get them rectified as far as possible, and what was done is recorded in the Annual Report for 1870. "Your committee have had the building painted and coloured throughout, have done away with all the old bedsteads, and replaced them with iron ones without curtains. Palliasses and hair mattresses have been provided in the place of the old feather beds, and all other furniture likely to retain infection has been removed. In fact, the wards have been almost entirely re-furnished. Your committee have also had all the drains opened and double trapped at all the gratings and down spouts, and all cesspools filled with concrete. The wards have been thoroughly fumigated with chlorine gas and every means has been used to get rid of all infection." The result was that, from the re-opening on Sept. 21st to the end of the year, 103 women were confined with only one death, reducing the mortality for the whole year to 1 in 25. In 1873 it was 1 in 50, and in 1876 and 1877, the two years taken together, 1 in 45, so that, on Nov. 24th, 1877, the medical officers again appealed to the committee to close the hospital. This was done on Dec. 1st. "It was resolved that Dr. de Chaumont of Netley be requested to inspect the hospital, and report on the ventilation and drainage with a view to their improvement." The result of this was that great alterations were made, at an outlay of upwards of £4,500. The hospital, in its reconstructed form, was re-opened on April 16th, 1879, after having been closed for sixteen months—and with what result? 287 women were delivered during the remainder of the year with only one death. But what a crushing disappointment came next year (1880); twelve deaths among 383 women delivered—one in thirty-two; and eleven of these were in the first half of the year, out of 196 deliveries—one in nineteen. Does not this bear out the opinions I have expressed in the earlier part of my address as to structural improvements.

In the following year, 1881, there was again a large expenditure in this way, nearly £600, and with what result? At a meeting of the committee held on April 28th, 1882, the medical staff reported that the sanitary condition of the hospital was very unsatisfactory and recommended that it be closed at once. The committee then resolved forthwith to act upon the advice of the medical officers, and appointed a sub-committee to inquire into the cause of the evil complained of. After several meetings the sub-committee presented a report to a special Court of Governors on June 2nd, recommending that the hospital be pulled down and rebuilt. Fancy this, after a recent expenditure of upwards of £5,000 on the buildings. The special court, however, took exception to this report and passed a resolution appointing a sub-committee from among the governors to coöperate with the committee of management "to report upon the present system of management adopted at the hospital." After several meetings the following report was presented: "It is recommended that the hospital be thoroughly inspected as to sanitary arrangements, and that it be at once cleansed, whitewashed, &c., and re-opened as soon as possible, and that it be closed for thorough cleansing for a month every year. That the back part of the hospital be pulled down and a one-storeyed building be put up, together with other alterations, at a cost not exceeding £1000." This was done and the hospital was partially re-opened on Oct. 1st, after having been closed for five months.

But, little more than five months later, on Feb. 17th, 1883, in consequence of the unhealthy state of the wards, the committee, on the recommendation of the medical staff, again closed the hospital and appointed a sub-committee to inquire into the sanitary condition of the hospital generally. Their report was to this effect: "That, as far as the construction of the hospital is concerned, no alteration is required. That certain improvements recommended by Dr. Pavy, the medical officer of health, be effected as regards the soiled linen shoots. That the wards be at once disinfected, cleaned, and whitewashed, and that the hospital be re-opened as soon after April 1st as possible." There were some other less important recommendations. The hospital was re-opened on April 20th, and between that date and the end of the year 209 women were delivered with but two deaths, 1 in 104, and yet, in the two years 1882-83 taken together, the mortality rose to no less than 1 in 23. In 1884-85 combined it was 1 in 48. In 1886, up to the closure on May 14th, 3 women died out of the 133 delivered, 1 in 44; and now we come to the period when the sublimate treatment commenced.

From the re-opening under its beneficial influence on July 1st, 1886, to Sept. 30th, 1887, 420 confinements took place without any death. From the same date, July 1st, 1886, to Dec. 31st, 1896 (ten and a half years) 4608 women were delivered with 11 deaths: mortality 1 in 419, or 2·387 per 1000. From Jan. 1st, 1892 to Dec 31st, 1896 (five years), 2392 deliveries with 3 deaths—1 in 797 = or 1·250, i.e., 1¼ per 1000, and these deaths were: 1. Sudden death in 1893 from pulmonary embolism on the third day after delivery (patient had shown no signs of illness up to the occurrence; and the report of the necropsy by Dr. Tooth, Demonstrator of Morbid Pathology to St. Bartholomew's Hospital, was "embolism of the pulmonary artery; no septic condition present.") 2. The second death occurred in 1894, from puerperal eclampsia, and took place on the third day after delivery. 3. The third death occurred in 1895 from puerperal eclampsia the day after delivery. So that we have in 1892, 487 deliveries with no death; in 1893, 430 deliveries with 1 death from pulmonary embolism; in 1894, 492 deliveries with 1 death from eclampsia; in 1895, 490 deliveries, with 1 death from eclampsia; in 1896, 493 deliveries with no death. Such a low rate of mortality as this one cannot expect to maintain, when it becomes a matter of fortune how many deaths from non-preventable causes may arise, such as the three from eclampsia and pulmonary embolism met with in the last five years. Only on Dec. 26th last I was called to the hospital to a severe case of eclampsia; the patient has happily recovered, but had she died it would not have enabled me to say we had had no death in the year 1896, and it would have increased the rate of mortality in the last five years.

Thus it will be seen that in the last five years among 2392 deliveries there has been no death in which septicæmia could have borne any part; and there has been also very little illness during this time. In the past year I have only been asked to see one patient who had a high temperature, and she was discharged quite well. I am assured that all the patients have been in a satisfactory state of health before they were allowed to leave the hospital. A total mortality of 1¼ per 1000 is, indeed, I think, something to be proud of—5 in 4000—and no death from septic causes. This seems to justify the title of Dr. Cullingworth's address, "Puerperal Fever a Preventable Disease"; rather different to the time of my introduction to the City of London Lying-in Hospital, when 1 in 19 was dying.

I do not dispute for one instant the great share that cleanliness plays in these results. My late colleague, Dr. Matthews Duncan, spoke of antiseptic precautions as transcendental cleanliness.[4] He had, he said, always defended the good or the better hospitals, and he was proud to know that now, when thoroughly antiseptically managed, they needed no defence. Their mortality was equal to, if not less than, that of private practice. During his whole life he (Dr. Matthews Duncan) had watched the generous and persevering attempts of his brethren to improve midwifery hospitals. Long ago, in Dr. Rigby's time, he came to London and saw a great ventilating scheme which was to work wonders. Architectural arrangements, drainage, ventilation, segregation and drugs had all been tried and all without securing success. The mortality in hospitals was terrible. He did not know what it was in private practice; probably it was as bad, or nearly as bad, as in big hospitals. Antiseptics, and antiseptics alone, had brought success and had sustained success. It was, he knew, common in highly respected quarters in London to attribute this modern success or diminished mortality in general hospitals, as in lying-in hospitals, to many factors—to improved feeding, housing, cleanliness, nursing, and antiseptics; and no doubt all were important, but all had failed till the antiseptic era, and all would fail again were antiseptic precautions—transcendental cleanliness—neglected. In his valuable book, "Mortality of

[4] Transactions of the Obstetrical Society, vol. xxvii, p. 215. Discussion on Dr. (now Sir) W. O. Priestley's paper, Antiseptics in Lying-in Hospitals.

Hosted by Google

Childbed and Maternity Hospitals,[5] Dr. Matthews Duncan says: "In a well-managed hospital they die at the rate of 1 in 100; all the country over the mortality is probably not much less, in the best private practice it appears to be greater." "In the years of my private practice of which I have preserved records I find 8 deaths in 736 cases, or 1 in 92." This was written in 1870, before antiseptic midwifery came in practice.

Why the sublimate treatment should not be adopted in private practice as well as in hospitals I am at a loss to understand. In my lecture to the midwives that I have spoken of, given in 1887, I gave them a list of what I order to be ready in the house of every patient who expects me to attend her in her confinement, and amongst the things was what would make half a gallon of sublimate solution (1 in 1000), labelled "To be used with an equal part of hot water as a lotion"; and I have continued this, very much to my satisfaction, ever since, and I have used the irrigation just as in the hospital practice and have never seen a sign of mercurial poisoning. In July, 1881, I had the great misfortune to lose my first private patient, and from puerperal septicæmia. This was before the days of sublimate and sterilising instruments, but not before the introduction of other antiseptics, and every precaution had been taken by the use of carbolic lotion and carbolised cream. It was a forceps delivery after forty hours labour in a primipara; an occipito-posterior presentation; and the perineum was partially ruptured. She became feverish after a rigor on the fourth day and died on the thirteenth day after delivery. The most unremitting attention failed to save her life. I cannot tell you the distress the loss of this patient—a young wife—caused me. Only those of you who have had similar losses can realise what it was. I told you in my address last January of a case of puerperal peritonitis in a patient delivered in December, 1890, who was attended by me under the most strict sublimate lines. It was a genuine case of acute septic peritonitis occurring a few hours after delivery, and although no necropsy was made, I feel convinced, from the reasons I gave you, that it was caused by rupture of a pyosalpinx, as in those cases narrated by Dr. Michie of Nottingham in his paper read before this society in May, 1885.[6] If this case be excepted, no case of septicæmia has occurred in my private practice since I commenced the use of corrosive sublimate. It gives me a feeling of protection I cannot over-estimate. I feel sure if its employment in midwifery were generally adopted by practitioners for their hands and for vaginal irrigation the Registrar-General's reports of the mortality from puerperal septicæmia would very soon show a difference, and in these days of portable compressed drugs there is no reason why it should not be almost universally used, even among the very poor. To my mind it would be a great pity if Dr. Bantock's recent reference to mercurial poisoning were to deter practitioners from employing it. It is only right, however, that it should be pointed out to them what may result if it be *improperly* used.

In the annual report of the General Lying-in Hospital for 1883 the medical report, signed by Dr. (now Sir John) Williams and Dr. Champneys, says that 342 women were confined, of whom 3 died (1 in 114), 2 from septicæmia, quite independent of one another, "a percentage which testifies to the healthy condition of the hospital." This was during the time that antiseptics were employed there, but, you will note, before the corrosive sublimate was commenced, and the committee add in presenting this medical report to the governors: "The committee beg to tender their congratulations to the eminent surgeon to the hospital, Sir Joseph Lister, Bart., to whom this and other institutions are so much indebted for the satisfactory medical results obtained through the system with which his name is associated."

Sir William Priestley concluded his paper read before the Obstetrical Society of London in July, 1885, entitled "Notes of a Visit to some of the Lying-in Hospitals in the North of Europe; and particularly on the Advantages of the Antiseptic System in Obstetric Practice," with these words: "Ample funds and sufficient space are necessarily most potent aids in waging warfare with disease in hospitals, but, even with limited means and space, absolute cleanliness, *supplemented by the antiseptic system*, may in our own country have a large influence for good, and the labours of our illustrious Lister prove of equal value to the obstetrician as to the surgeon. If I am not mistaken some of our Fellows," says Sir William Priestley, "can tell us of triumphs of this kind in the lying-in hospitals of London." I hope you will think that I have this evening succeeded in doing so.

I feel that I cannot conclude my address better than by saying that though numerous peerages have been conferred upon those "waging warfare" resulting in the *destruction of life* and victory (!) never has one been more worthily bestowed than on "our illustrious Lister" for the victory gained by him in "waging warfare with disease in hospitals," resulting in such an enormous *saving of life* among our fellow creatures.

I cannot sit down without congratulating the society upon its selection of my successor in this chair. Professor Mayo Robson will fill it, I am sure, with dignity, eloquence, and good judgement, that have never, at all events, been surpassed by any of his predecessors.

In bidding you farewell, I thank you all for the kindness you have displayed towards me and the assistance you have given me during the two years that I have presided over you, a period in my life of which I shall always have the happiest recollections.

SYPHILITIC DISEASE OF THE HEART WALL.

BY SIDNEY PHILLIPS, M.D., F.R.C.P. LOND.,

PHYSICIAN AND JOINT LECTURER ON MEDICINE AT ST. MARY'S HOSPITAL; SENIOR PHYSICIAN TO THE LONDON FEVER HOSPITAL; PHYSICIAN TO THE LONDON LOCK HOSPITAL.

A PROFESSIONAL man, aged fifty-three years, who in his youth contracted syphilis had from time to time been troubled with sores on the tongue, and in 1890 suffered from epileptiform convulsions, of which a grave prognosis was given by the physician whom he consulted, but which gradually ceased to occur. A child of his had been under treatment by a well-known surgeon for psoriasis suspected to be of syphilitic origin. At Easter, 1894, while on a few days' holiday in the country, he went to bed apparently quite well, but was suddenly taken ill in the night. The physician who was called to see him has kindly given me the following account of his symptoms: "He was walking about the room in an agony of pain which he described as unendurable. The lower part of the sternum and epigastrium were the chief seats of pain, which went through to the back and also extended down the left arm; there was no marked pallor, no cyanosis, no laboured breathing; the pulse was 60 and laboured; there were no signs of valvular mischief about the heart and no irregularity of rhythm; there was a sense of distension of the abdomen. I ascertained this was the first attack of severe pain he had had, but there had been previously some discomfort and some pain running down the arm, and that his heart had been suspected of being at fault." Recovering under the free administration of morphia, he returned to town and to work against medical advice; but eighteen days after this attack of pain, on returning home from business, he quietly expired in an arm-chair while reading the evening paper.

I made the necropsy with the medical man who had attended him from time to time in London. There were no signs of disease anywhere, except that there were about two drachms of clear fluid in the pericardial sac and some soft bands of fresh lymph about half an inch long, easily broken across, extending from the anterior wall of the left ventricle just above the apex to the adjacent surface of the pericardium; on the surface of the ventricle beneath the lymph was a small area of ecchymosis the size of a shilling. The heart wall in this situation felt harder than elsewhere, and on section this thickening was seen to be produced by a yellow homogeneous-looking substance much resembling in appearance the almond of a wedding-cake. It was situate between the endocardium within and the pericardium without, entirely replacing the muscular fibre, and formed a nodule with a diameter of that of a florin in the anterior wall of the ventricle, which it thickened and toughened. The rest of the heart and the cardiac valves were healthy, except that the left ventricle was somewhat dilated. Mr. J. J. Clarke, pathologist to St. Mary's Hospital,

TABLE OF FATAL CASES OF SYPHILITIC DISEASE OF THE HEART WALL.

No.	Reference to case.	Sex and age.	History of symptoms.	Post-mortem appearances.
1	Ricord: Clinique Iconographique, 1851.	M. 41.	Chancre ten years before he came under treatment for tertiary cutaneous ulceration; improved under iodide of potassium for eleven days. Sudden faintness and cyanosis; said, "I feel very ill," and died in five minutes.	Heart hypertrophied; clots in both ventricles; lymph on pericardium; patches of infiltration in the wall of both ventricles, especially of the right; some hard, like scirrhus, others softening, with complete destruction of muscle fibre; old ecchymoses in wall of left ventricle.
2	Virchow: La Syphilis Constitutionelle, 1860.	M. 47.	Chancre fourteen years before; intense dyspnœa; lividity of face and extremities; respirations 48 per minute; signs of moderate hypertrophy of heart: systolic bruit at apex; death after three days of acute illness.	Left ventricle dilated and a diverticulum the size of a nutmeg near its apex with thickened endocardium and adherent thrombus; the two papillary muscles quite shrivelled; general fibroid infiltration replacing the muscle wall in right ventricle, some gummata, and an aneurysmal dilatation below the tricuspid valve, but the left ventricle chiefly affected; pericardial adhesions.
3	Lancereaux.	M. 29.	Syphilis evident from the post-mortem lesions in kidneys and liver; suffered during life great dyspnœa, fatigue, vertigo, giddiness, epileptiform attacks, palpitation, and œdema; signs of enlargement of heart; feeble pulse; ill some months; sudden death.	Left ventricle dilated and thickened extensively by an infiltration chiefly about base of the heart and mitral orifice; columnæ carneæ involved; gummata scattered in the infiltration; endocardium attacked.
4	Lancereaux.	F. 44.	Violent palpitation; fits of suffocation getting increasingly severe; violent pulsations of heart with very feeble pulse; great engorgement of veins; vomiting; systolic bruit; death from right ventricle failure.	Left ventricle healthy; right ventricle dilated and infundibulum the seat of tough infiltration stiffening its wall; in its substance little nodules (gummata) "like small-pox eruption"; rest of ventricle healthy.
5	Burney Yeo: Transactions of the Pathological Society, 1874.	—	—	Gummata involving the musculi papillares and cordæ tendineæ of left ventricle.
6	W. Cayley: Transactions of the Pathological Society, 1875.	M. 28.	History of syphilitic infection some years previously; found dead in bed: he had gone to bed in his usual health after taking from 20 to 30 grains of chloral, which he had been in the habit of doing.	Left ventricle hypertrophied, and in its wall several round nodules were projecting into the cavity of the ventricle as well as externally and involving the bases of the musculi papillares.
7	A. P. Gould: Transactions of the Pathological Society, 1877.	M. 40.	Date of infection unknown; for some time dyspnœa and cardiac pain; fell dead in a public-house after walking across some fields when in apparently good health.	Left side of heart quite healthy; right ventricle normal thickness, all trace of muscle fibre in it replaced by a whitish infiltration; it involved the septum and many of the musculi pectinati.
8	T. Barlow: Transactions of the Pathological Society, 1877.	M. 42.	Three years after infection anginal attacks lasting till death two years later; for one year before death orthopnœa, cough, swelled feet, systolic and diastolic bruits, signs of right heart engorgement.	Syphilitic infiltration of wall of left ventricle around aortic orifice and formation here of aneurysm of heart wall; not ruptured.
9	Mannino: Jornale Italiano, 1882.	M. 36.	Seven years after infection illness with dyspnœa, cough, albuminuria; systolic bruit at apex, especially over right ventricle; diagnosis of syphilitic heart disease from peculiar feeble contraction of heart and empty arteries; syphilitic skin eruption; died suddenly after nine days' illness.	Infiltration of large fibroid patches, creaking on section, in anterior wall of both ventricles; a hard fibrous cord in septum; left ventricle chiefly enlarged.
10	Henderson: Transactions of the Pathological Society, 1882.	M. 30.	Was in good health; suddenly staggered and fell, put hand to heart, and died in a few minutes; no history of angina.	A mass of fibroid tissue in the septum 2 × 1½ inches thick and muscular substance permeated by gummatous nodules; narrowing of lumen of coronary arteries; nodules in pericardium over left ventricle.
11	Goodhart: Transactions of the Pathological Society, 1887.	M. 30.	Date of infection unknown; had had a sore throat and eruptions and node on tibia: after being apparently well and quite cheerful in the evening died in his arm-chair the same night, as if he had been sleeping; a prescription for mercury found in his pocket dated nine months previously.	Gummatous infiltration of the muscle of the left ventricle, which, forming an aneurysm, had ruptured into pericardial sac.
12	Goodhart: Transactions of the Pathological Society, 1887.	F. 30.	Dropped dead in the street; supposed to have been a prostitute.	Left ventricle dilated and hypertrophied; it and the septum the seat of syphilitic infiltration.
13	Turner: Brit. Med. Jour., 1890, vol. i., p. 657.	M. 37.	Infection ten years previously; for some years precordial pain, palpitation, giddiness; increased four days before admission to hospital; cardiac dulness extended to right; rough systolic murmur at base of heart; pulse 52 and getting slower down to 40, when he died from syncope four weeks after admission to hospital.	Infundibulum three-quarters of an inch from the pulmonary valves surrounded by, and considerably contracted by, infiltration and projecting into left ventricle; left coronary artery blocked by a thrombus; gumma in testis.
14	Pitt: Transactions of the Pathological Society, 1891.	M. 28.	Had had slight pain in heart, but not enough to give up work; died suddenly while lifting a weight.	Gummatous cellular infiltration involving both ventricles, especially the left; aneurysm of posterior wall of left ventricle near apex, which had ruptured; syphilitic testis.
15	Holleston: Transactions of the Pathological Society, 1893.	M. 34.	Death from an accident.	In right ventricle and in septum ventriculorum were many gummatous nodules; gummata in testis, and scars on penis and groin.
16	Sharkey: Transactions of the Pathological Society, 1885.	M. 44.	History of syphilis; epigastric pain, cough, short breath, feeble pulse, general dropsy.	Heart enormously hypertrophied, but very thin near apex of left ventricle, and here aneurysmal sac had formed.
17	McNalty: Medical Times, 1870.	M. adult.	Died from aneurysm of aorta.	Heart somewhat atrophied, with numerous gummata in its wall from size of a pin's head to a pea; pericardial adhesions.

TABLE OF FATAL CASES OF SYPHILITIC DISEASE OF THE HEART WALL—*continued.*

No.	Reference to case.	Sex and age.	History of symptoms.	Post-mortem appearances.
18	Moxon: Transactions of the Pathological Society, 1874, quoted by Fagge, and Guy's Hospital Reports, 1867.	M. (?)	Suddenly reeled and fell dead whilst walking across London-bridge.	Left ventricle, extensive fibroid disease; nodes of tibiæ; gummata in liver and diaphragm.
19	Fuller: Transactions of the Pathological Society, 1868.	M. 45.	Died suddenly ten minutes after having a fit in bed in a workhouse to which he had been admitted a few hours before; had gone to bed apparently well.	Extensive fibroid infiltration of wall of left ventricle completely destroying its muscular tissue; gummata in right ventricle.
20	Haldane: Edinburgh Medical Journal, 1868.	F. 25.	A prostitute who, soon after eating a good supper and appearing well, died while walking downstairs.	The septum entirely destroyed by syphilitic infiltration and so also part of the wall of left ventricle; gummata in right ventricle; no other signs of syphilis.
21	Phillips: Case above recorded.	M. 53.	Infection many years previously; had had syphilitic skin eruption and other symptoms of constitutional syphilis; anginal attack eighteen days before sudden death while reading in an arm-chair.	A gumma the size of pigeon's egg in left ventricle anterior wall close to apex of heart, destroying muscular fibre and setting up slight local pericarditis.
22	Lebert.	——	Date of infection unknown, but syphilitic skin eruption, necrosis of palate and nodes on scalp; a systolic bruit.	In right ventricle close to pulmonary valves two gummata and a third a little way off; endocardium thickened over the gummata.
23	Kronig: Berliner Klinische Wochenschrift, November, 1895.	M. 33.	Oppression eight days; irregular pulse; increased cardiac dulness; systolic brutt at left apex; died whilst getting quietly into bed.	Gummata in left ventricle; aneurysmal bulging and rupture of the left ventricle near septum; the aneurysmal bulging projected septum into right ventricle.
24	London Hospital Museum, No. 1420.	M. (adult).	Distinct history of syphilis. Suddenly dropped dead while singing a song; until that moment was to all appearance in perfect health.	A soft, lobulated, gummatous growth in muscular wall of left ventricle.
25	Sir D. Duckworth: Transactions of the Clinical Society, 1895.	M. 33.	Suddenly fell in the street and expired when carrying his little boy.	Evidences of previous syphilis on tongue and glans penis. Gumma in left lung; recent gummatous growth at base of left ventricle, and an older gumma near heart's apex.

found the yellow material to present the usual appearances of gummatous tissue; the heart is now in the museum of the hospital.

So long ago as 1842 Ricord[1] described two cases of syphilitic disease of the heart wall, and in his "Clinique Iconographique," Plate XXIX., he gives an admirable coloured illustration of a syphilitic heart lesion very similar to that I have just recorded. Virchow in 1860[2] described other cases, and Oppert[3] in 1868 was able to collect eight recorded cases of gummata of the heart. Since then from time to time post-mortem specimens of the affection have been exhibited at the Pathological Society of London and elsewhere. The table given above shows abstracts of the history, where such was obtainable, and of the lesions found in twenty-five cases. In all these cases the pathological changes consisted in a deposit in the muscle of the heart of a substance which in the early stage was soft and yellow in colour and occurred either as nodules, varying in size from that of a pin's head to that of a large marble, or as a more or less widespread infiltration; the substance destroyed and replaced the cardiac muscle so that eventually not a trace of muscular fibre could be detected; it sometimes projected the endocardium lying over it within the heart or the visceral layer of pericardium on the outside of the heart. The infiltration in many cases resulted in a great thickening of the heart wall, producing a false hypertrophy; in other cases it so weakened the heart wall that it yielded to the intra-cardiac pressure and dilatation resulted, the heart wall in extreme cases being greatly attenuated; occasionally there was produced a *local* extrusion of the thinned cardiac wall, giving a cardiac aneurysm. In some of the cases of cardiac syphilis the infiltration became white in appearance and tough in texture, creaking on section, and where widely deposited it caused the heart wall to become stiff and to gape on section. In one recorded case a gummatous nodule softened and discharged itself into the heart's cavity, but such an occurrence is quite exceptional. The deposit, whether nodular or diffuse, occurred in the septum of the heart or in one or both of the ventricles. The cases recorded are not numerous enough to base an estimate upon of any value as to the relative frequency of the affection on the two sides of the heart. Any part of the ventricle wall may be affected; the base, it would appear, rather the most often. In some cases the deposit was close to the heart's apex, as in the case at the head of this paper. The infiltration frequently extended into the columnæ carneæ, softening them or causing their rigidity or contraction, and in one case leading to union of adjacent musculi papillares. The pericardium was occasionally the seat of gummatous nodules, and local pericarditis arose occasionally over these nodules.

The microscopic changes in all these cases were similar to those found in syphilitic fibroid and gummatous changes in other parts of the body. It will have been seen, too, that syphilis produces the same gross changes in the heart as it does in other internal viscera, for example, the testis—viz., a general fibroid infiltration or gummata or both together. In the heart the essential change which syphilis produces is a replacement of the muscular tissue by a round-celled fibroid tissue which, whether it occur as nodules only or as a more widespread change, leads to dilatation or hypertrophy or merely rigidity of the heart wall, and has this uniform result, that it impairs or interferes with the heart's contraction. Now diffuse fibroid change in the heart wall occurs no doubt from other causes than from syphilis, and, as was pointed out by Fagge,[4] it is not possible to tell by examination after death whether the changes are or are not of syphilitic origin, except in those cases where there are actually gummata. But in the cases I have included in the table as the basis of this paper there was in every one a distinct history of syphilitic infection, or there were syphilitic changes in other organs than the heart, or there were actual gummata in the heart wall. These cases, therefore, may be taken as undoubted examples of syphilitic heart disease.

SYMPTOMATOLOGY.

Most of the cases have been recorded to illustrate the pathological conditions produced in fatal cases and comparatively little attention has been directed to the nature of the symptoms produced by syphilitic disease of the heart wall during life; but Ricord, Lancereaux, Mannino, Buchwald, Semmola, and others have written upon the clinical aspects. Lancereaux writes: "Syphilis of the heart is recognisable by a grouping of symptoms, which are palpitation, dyspnœa, and then, as little by little the heart dilates, a systolic bruit develops and later anasarca." Buchwald[5] describes the symptoms as "headache, dizziness, flashes of light, loss of strength, palpitation, dyspnœa, feverishness, sore-throat, and in some cases symptoms of angina pectoris and neuralgic pains like aneurysm; the cases in which the heart insufficiency can no longer be influenced favourably quickly run downhill, developing marked anæmia

and consecutive kidney disease and sometimes pulmonary hæmoptysis. The majority of cases show a great and rapid improvement under anti-syphilitic treatment." Semmola[6] writes: "Syphilis is one of the most troublesome and ill-defined pathogenic diseases of the heart, commencing not with direct functional disturbance, but with vague nervous diffuse phenomena without certain features of recognition; neither percussion nor auscultation will assist the investigator in the incipient stages of the disease; the morbid process is slow in progress, exhibiting manifestations of a change in the ventricular structure without evidence of dilatation or hypertrophy; the absence of the latter makes the clinical picture of the morbid changes difficult to reconcile with the more commonly met with cardiac diseases." These descriptions, though agreeing to some extent with one another, make no distinction between the widely varying conditions producible by syphilitic disease of the heart. There may be only a gumma, or a widespread general infiltration, or extensive dilatation or hypertrophy, or a cardiac aneurysm on either or both sides of the heart, and it is obvious, therefore, that no one description of symptoms can be given which will be applicable to all cases.

In this paper I propose to inquire whether the symptoms of syphilitic disease of the heart wall are sufficiently distinctive to enable us to make an approach to a correct diagnosis of the condition during the lifetime of the patient.

Symptoms produced by gummata of the left ventricle.—In Case 15 in the table, in which death occurred from the effects of an accident, and in Case 17, where it resulted from an aortic aneurysm, numerous small gummata were found post mortem in the heart wall, and in the Museum of the Royal College of Surgeons of England is a very beautiful specimen (No. 2959) of a heart with gummata the size of a pea in its wall; the patient from whom it was taken had been under observation for a considerable period for symptoms of cerebral syphilis, from which he died. In none of these cases had there been any symptoms of heart disease during life, and in none of them did death occur from the heart affection. It is evident, therefore, that very small gummata may exist in the heart wall without giving any recognisable evidence of their presence. So long, however, as they remain so small in size or so situated as to produce no symptoms they do not appear to be dangerous to life or of immediate importance. But the importance of gummata of larger size in the left ventricle is very great, for they may cause sudden death in the prime of life in otherwise healthy persons, as shown by the case at the head of this paper; by Case 24, where a man dropped dead after singing a song, having been to all appearances in perfect health until that moment; and by Case 25, of a man aged forty-five years, who, when walking in the street carrying his little boy, suddenly fell down and expired.

In all these cases there was a gumma in the left ventricle, and it is noteworthy that necropsies show that it is only when the gumma is in the *left* ventricle that it is liable to produce such sudden death and also only when it is situated near the apex of the ventricle; this, indeed, is what might be expected from what is known of the action of the muscular fibres of the ventricles during systole. Now, although persons may thus die suddenly from cardiac gummata in the midst of apparent health, it must not be concluded they had previously suffered from no symptoms or signs of heart disease. In such cases it is often impossible to obtain the patient's previous history or to ascertain if he had suffered from any symptoms, and most of the recorded cases were exhibited as pathological specimens with little reference to the previous condition of the patient. It is, therefore, not justifiable to infer that these patients had suffered from no symptoms indicating heart disease because no evidence of such is forthcoming. The case at the head of this paper, for instance, might have been regarded as one of sudden death without any previous cardiac symptoms had it not been that information was subsequently obtained that the patient had a few days before, when away from home, been seized with sudden intense pain, regarded at the time as of gastric origin, but which the after evidence leaves no doubt was a very acute attack of angina pectoris. And in all the cases recorded of sudden death from a cardiac gumma in which the previous condition of the patient has been ascertainable there have been symptoms, slight it may be, often intermitting, often wrongly interpreted, but which might, if our knowledge of the subject was more accurate, have given rise at any rate to a strong suspicion of cardiac syphilis. It is, therefore, of importance to inquire further what are the exact indications which a cardiac gumma may produce.

The fatal cases of cardiac gummata in the table do not lend much assistance, the patients having died under circumstances which prevented the previous history being accurately ascertained. But in Case 21 the patient had been under careful observation for a long time and there had been nothing more than an attack of angina pectoris, palpitation, and occasional discomfort about the heart, with such slight physical signs of abnormality that it was thought heart disease might be excluded. From this case and from the evidence of other recorded cases in which the symptoms cleared up under anti-syphilitic treatment, and in which it was presumable that gummata existed, the symptoms producible appear to be one or more of the following: palpitation; subjective sensations about the precordium; attacks of angina pectoris; giddiness, faintness, or actual syncopal attacks; epileptiform seizures; and alterations in the force and frequency of the pulse, especially its great rapidity, and in some cases irregularity of the heart's action. The symptoms may be variously associated; there may be only angina, or palpitation and angina, or tachycardia, or palpitation and syncopal attacks, or they may be grouped in other ways. With these symptoms there are no evidences that the heart is enlarged, but there are usually some physical signs of cardiac action being embarrassed—the heart's impulse may be feeble and the first sound weakened, but more often the action is irregular and excited and the impulse abrupt, with a loud first sound; and it is quite possible that a gumma, which is virtually a foreign body in the heart substance, may impede the free action of the muscular fibres immediately around it and give rise to over-action of the healthy fibres of other parts of the ventricle.

None of the symptoms which have been enumerated are pathognomonic of cardiac gummata, but there are two of them—viz., angina pectoris and tachycardia—which merit special attention in this connexion.

Angina pectoris.—Angina pectoris is usually associated with physical signs or symptoms of heart or valvular disease that can leave no doubt that the angina is dependent on the heart condition; but, as many of the cases in the table show, a gumma of the heart wall may produce angina pectoris with scarcely any other symptoms or signs of heart disease. Thus, in Case 8 what was subsequently verified as true angina pectoris was for a whole year the sole symptom of an eventually fatal syphilitic heart lesion, and in Case 21, except for some occasional palpitation, an attack of severe angina pectoris was the sole symptom of a cardiac gumma which killed the patient eighteen days later. When anginal pain occurs then, even though there be no confirmatory signs of heart disease, we should remember that it may be the indication of a gumma in the heart.

There are some other conditions which will produce anginal pain with a similar minimum of confirmatory symptoms of heart disease—viz., fatty degeneration of the heart and, as Sir William Broadbent has pointed out, aneurysm at the very root of the aorta within the pericardial sac; also aneurysm of the cardiac wall, of which an example will be given later. The cases in which angina is due to fatty disease can be distinguished from those in which it is due to a gumma, by the fact that fatty disease occurs for the most part after five years of age and syphilitic heart lesions for the most part much earlier in life. Fatty heart is also usually associated with other clinical evidences of its presence, and in syphilitic gummata there will be evidences, or history, of previous infection. The other condition from which cardiac gumma may have to be distinguished is aneurysm at the root of the aorta. Sir William Broadbent[7] points out that "it is not always possible to distinguish between anginoid pain due to aneurysm in this situation and true angina; in the cases of aneurysm the sense of impending death is not so marked a feature of the attacks, and the pain often radiates down the arms instead of along the left only, occasionally it shoots down the right arm only. In angina there may be no physical signs of disease of the great vessels; in aneurysm there will be the the ringing second sound and very frequently a diastolic murmur."

Angina pectoris, then, must not be discarded as a symptom

Hosted by Google

of heart disease because it is unaccompanied by any other evidences of heart disease; and where fatty degeneration of the heart and aneurysm of the root of the aorta can be excluded it affords a presumption of gumma or aneurysm of the heart, and when on investigation any syphilitic antecedents are discovered in the patient the presumption becomes a strong probability.

I need not enter into the differential diagnosis between gumma and aneurysm of the heart wall, as they are, in fact, stages of the same affection.

Tachycardia, according to Semmola,[8] is another symptom which sometimes denotes a cardiac gumma, and "it may be," he writes, "the earliest sign of syphilitic disease of the heart wall." He also adds: "The rapid action is constant and not paroxysmal as a mere neurosis; this is important to recognise, because it is at this period that anti-syphilitic treatment is of most avail." A case recorded by the late Dr. Bristowe[9] appears to support the observation. A man, aged thirty-eight years, after contracting syphilis, began to suffer from tachycardia, with epigastric pain, but without physical signs of heart disease. He was little relieved by digitalis or iron, and later developed dyspnœa, anasarca, and dilatation of the heart and died in about a year. No necropsy was made, and the connexion between syphilis and the symptoms does not appear to have been entertained, but the course of the case so exactly resembles that of many of the cases in the table of verified syphilitic heart disease that it appears highly probable that Dr. Bristowe's case was one of syphilitic myocardial change of which the tachycardia was one of the earliest symptoms. I have no case in which tachycardia was verified by post-mortem examination to have been due to gumma; but in a case which I shall describe later, and in which the post mortem examination showed general fibroid change in the heart wall, tachycardia was one of the earliest symptoms and probably, therefore was produced when the fibroid change was quite localised. This case, however, does not bear out Semmola's dictum that in such cases the tachycardia is constant and not paroxysmal.

It is evident that where tachycardia is an early symptom of fibroid heart change it must be very difficult, or even impossible, to distinguish such a case from a mere functional tachycardia, but it is highly probable that many cases of so-called functional tachycardia are really due to some organic lesion, such as a gumma in the heart, and so also are some of those cases described in young soldiers as "irritable heart."

Gummata of the right ventricle.—The post-mortem examinations of the cases in the table show that gummata may occur in the right ventricle as well as in the left. So far as I can ascertain there is no recorded case of death, either sudden or gradual, from a gumma in the right ventricle; it is, therefore, not possible to say, from post-mortem evidence, what symptoms a gumma in the right ventricle may produce. Though not so immediately dangerous to life as gummata of the left ventricle, they are, however, by no means unimportant, for they may interfere with effective action of the right heart, and they tend in time to become aneurysmal and to rupture, or they may become associated with more widespread fibroid disease.

In all the cases in which extensive fibroid disease has been found in the right ventricle *dyspnœa* has been one of the earliest and most constant symptoms; it is, therefore, probably producible when there is only a gumma or fibroid change of limited extent on the right side of the heart. When dyspnœa occurs without lung disease or left-sided heart disease or other obvious cause, such as anæmia, it is well, therefore, to remember its possible dependence on some fibroid change in the wall of the right ventricle, and this becomes all the more probable if on enquiry we find a history, or signs of, previous syphilis. Angina pectoris, too, may no doubt result from such disease in the right, as it may in the left, ventricle.

The following appear to have been instances of cardiac gummata:—

CASE A. *Severe angina without physical signs of cardiac disease; recovery after anti-syphilitic treatment.*—A married man, aged thirty years, came to the out-patient department at St. Mary's Hospital on Aug. 12th, 1887. He had contracted a chancre, followed by a syphilitic eruption, twelve years before. Except for an attack of typhoid fever in 1884 his health had been good, but in 1877, or two years after his primary infection, he began to suffer from pains in the cardiac region; he got better, but for the four years previously to 1887, when I first saw him, he had been subject to attacks of angina which were very severe and in March, 1887, became still more intense. When I first saw him he was very tremulous, having had an attack the same morning; his pulse was 100 per minute, regular, and of good force. He described the attacks as "horrible sensations" felt in the cardiac region and along the course of the left ulnar nerve; during the attack he was afraid to draw breath. The attacks lasted for one or two minutes, but sometimes recurred in a minute or two; when over there was profuse sweating. He said that when the attacks had passed he was not short of breath and could get about very well, but palpitation came on if he walked fast or ran upstairs. The position of the heart's apex was very difficult to exactly localise; it appeared to be in the fifth space, half an inch below and quite one inch inside the nipple and was very feeble, while there was a curious throbbing over the right ventricle, and, indeed, over the whole chest; there was no bruit anywhere except at the right apex and at the base of the heart, where the first sound was covered by a thin, hollow, soft bruit, possibly hæmic, being also heard under the left clavicle; the second sound at the right base was short and clicking; the heart's action was very abrupt and forcible, but the pulse was weak, regular, and 100 per minute and the carotids were throbbing. He had been under treatment in America, in this country, and in Scotland. He showed me a large bundle of prescriptions he had tried, mainly of digitalis, which had at times given him temporary relief. Nitrite of amyl he had repeatedly tried but with no benefit. Of late his angina had been unrelieved by digitalis and he was obliged to give up work, his attacks getting more frequent; he had had four in the last fortnight. I ordered him six grains of iodide of potassium with one-sixteenth of a grain of bichloride of mercury three times daily. He had no attack of angina after this until Sept. 15th or thirty-four days. In this attack the pain was in the chest and down the left arm, but not far down; the attack was slight—in fact, "not worth speaking of"; the palpitation, he said, was much better; he had not been in the same flurried and faint condition as before; and the pulse was 76 per minute, full and soft. The apex of the heart was now one inch below the nipple and one inch inside its line. The impulse was feeble and the jarring tremor over the right ventricle much less; over the left ventricle was heard a weak rather prolonged first sound and a clear second sound with a good interval between them. Over the right ventricle the first sound was louder than before and without bruit and there was re-duplication of the second sound. The first sound was hardly audible at the right base. The heart sounds were not hurried as before and the carotids did not throb so demonstratively. He continued to take the medicine till Sept. 9th and greatly improved. On Sept. 17th, or eight days after he left it off, he "came over very bad, being frightened to draw breath," and the pain went down the arm. His pulse was 96 and there was a soft post-systolic bruit. His medicine was resumed but of increased strength; he again greatly improved. On Oct. 13th the apex was one inch inside his nipple, there was no bruit, and his heart appeared healthy, except that the first sound was weak; the pulse was 72, and he could get about well and take exercise freely. On Feb. 18th, 1888, I saw him again, when he was quite well. I have not heard of him since.

CASE B.—I might add another case in which a policeman suffered so severely from angina that he fell down while on duty. There was no bruit or ascertainable evidence of heart disease; his anginal attacks were of intense severity and occurred once or twice while he was at the hospital, on one occasion so severe that I had to take him indoors. Nothing but hypodermics of morphia relieved him. He had to leave the police force, as I found afterwards meeting him by chance in the street. It then occurred to me to put him on iodide and mercury and his angina soon became very much less.

CASE C.—In another case a gentleman, who suffered from anginal pain so severe as to prevent any exertion came under my care. He had been treated without effect by several practitioners, and as I also failed to relieve him he saw a well-known physician in consultation with me, but he did not improve. Digitalis, strychnia, and all treatment failed to relieve him, till one day he mentioned to me that he had had

[9] Brain, October, 1887.

Hosted by Google

syphilis. Iodide of potassium entirely cured him and he is now in perfect health.

CASE D.—A man, aged thirty-two years, came to the out-patient department at St. Mary's Hospital on Nov. 6th, 1890, complaining of pain in the cardiac region of some months' duration, worst in the early morning. There was a sudden vibratory cardiac impulse, with a drum-like, very abrupt first sound. His pulse was 72 per minute. He said directly he went to work he got palpitation and pain in the heart region. He had a sharply-cut syphilitic ulcer on the side of the tongue and had had a chancre some years previously. I ordered him mercury and potassic iodide, and on Nov. 13th the impulse was less vibratory, the pain and palpitation gradually lessened under the treatment, and he came to see me in reply to a letter of mine on March 4th, 1891; he was then able to work well and suffered no pain. The first sound was duplicated and the pulse 84 per minute.

CASE E.—A man, aged sixty-one years, came to me at St. Mary's Hospital as an out-patient on Nov. 19th, 1894, complaining of giddiness for three weeks, of sleeplessness, headache for fourteen days (very severe at night), and palpitation. The pulse was 138, small and running. The heart's apex was just inside the nipple line in the fifth space; there was a very rapid succession of first and second sounds and now and then a beat was dropped; the arteries were degenerate. The patient was very weak and anæmic and depressed. There was no albumin in the urine, the specific gravity of which was 1010. I ascertained he had had syphilis many years before and he had, indeed, some scarring of an eruption on the back. He took iodide of potassium and bichloride of mercury, and on Nov. 26th the giddiness had become less and he slept better. The headache also was less. His pulse was 160, very short, and with a slight tapping impulse. The heart sounds were regular. He felt much better and wished to resume work, but I advised against this. By Dec. 10th his pulse was 128 and tense; his first heart sound was loud and clear; he felt much better and went to work; and on the 31st the pulse was 104. He looked a different man; he ate and slept well, although there was occasional giddiness when he looked upwards and then suddenly downwards.

Diffuse syphilitic fibrosis of the heart.—Cases of *general* fibroid infiltration of the heart may be divided into two classes—those in which the weakened muscular tissue yields to the intra-cardiac pressure and dilatation results, and cases in which the heart wall becomes toughened, stiffened, and thinned, with much loss of power, but without dilatation.

Syphilitic fibrosis leading to dilatation of the heart.—When the *Left Ventricle* becomes thus dilated the evidences are the same as those of dilatation from other conditions—viz., subjective sensations about the cardiac region, even angina pectoris, giddiness, faintness, or actual syncopal attacks, with alterations in the force or frequency of the pulse, together with the physical signs of dilatation of the ventricle; the symptoms often are more marked than might be expected from the amount of dilatation present, probably because the fibroid change resists the dilatation to some extent, though itself greatly enfeebling the heart power; in these cases death may occur quite suddenly or only after dilatation of the right ventricle, back-working, and all the symptoms of tricuspid regurgitation have been produced; in some cases these right heart symptoms are due to independent involvement of the right ventricle by the fibroid changes. The table contains cases illustrating the effects of dilatation of the left ventricle from syphilitic changes In Case 3 death occurred after some months of well-marked symptoms of heart failure. and the left ventricle was found post mortem to be extensively dilated and hypertrophied, and in Case 12, where a woman dropped suddenly dead in the street, the left ventricle was found dilated and hypertrophied. When the *Right Ventricle* becomes dilated as a result of fibroid change the cases in the table show that suffocative attacks of dyspnœa, ascites, albuminuria with the physical signs and other evidences of tricuspid regurgitation occur, and death eventually takes place, but sudden death in the midst of apparent health does not result from fibroid disease of the right side of the heart. It must be, of course, remembered that where the left ventricle is affected by fibroid disease the right heart dilatation may be only a secondary result of this. Case 4 in the table illustrates the symptoms produced and the fatal results of syphilitic disease of the right ventricle with tricuspid regurgitation. The following cases are examples of dilatation of the heart, probably syphilitic, which improved under treatment.

CASE F.—*Dilatation of the left ventricle and syncopal attacks.*—A man, aged thirty years, was seen with Dr. S. de Butts on Oct. 12th, 1892; he was married and had three healthy children. He suffered in 1883 from a chancre and secondary syphilis. In 1891 he began to experience a dull pain in the lower sternal region with a feeling of constriction of the chest and palpitation; and one evening he had semi-syncopal attacks and had to lie down. He had to remain at home a fortnight. A month or six weeks before I saw him in October, 1892, after feeling much the same sensations as before, he had another semi-syncopal attack and was very breathless; he was just able to get into a cab and go home. No albumin was found in the urine either then or during the previous attack of illness. When I saw him the pulse was 84 per minute and the heart's apex in the sixth space, one inch outside the nipple line. The beat and first sound of the heart were very weak; the aortic sound was clear; the first sound was occasionally duplicated; there was no bruit; the heart was certainly dilated, and as he had not benefited by digitalis or strychnia, was in good general health, but had suffered from syphilis, the diagnosis of possible syphilitic change in the left ventricle was arrived at and he was ordered mercury and iodide of potassium; the signs of dilation rapidly closed up. Dr. de Butts tells me he has been well since then, except that once or twice the symptoms have recurred. Each time he has resorted to the same treatment and soon got well. About August, 1896, he had a sort of anginal attack, which he treated in the same way.

The following case is recorded by Lancereaux in his "Treatise on Syphilis," p. 393:—

CASE G.—A woman, aged thirty-seven years, entered the Hôtel Dieu for exostoses on the tibiæ. She had contracted syphilis six years before and it was evident it was to this disease that the exostoses were attributable; but she was, moreover, pale, emaciated, and her liver projected three fingers' breadth below the ribs. She had shortness of breath, a feeling of oppression in the precordial region, and violent palpitations. Percussion showed that the heart was enlarged and auscultation revealed a slight blowing sound; the movements of the organ were irregular and the pulse feeble and compressible. Not seeing anything to explain the derangements of the heart and liver he suspected that the lesions of those organs might be connected with syphilis and this opinion was afterwards confirmed by the effect of treatment with iodide of potassium.

CASE H.—In a second case recorded by the same author the patient, a young man, admitted to the Hôtel Dieu suffered from greatly enlarged liver, œdema of the extremities, and irregular movements of the heart, which did not appear enlarged, and without any abnormal sounds. For several months he had suffered from oppression on the chest. Despite the absence of any avowed antecedent syphilis he was put on iodide of potassium, and the oppression disappeared, the heart regained its regularity, and the liver diminished in size so as no longer to project by more than one or two fingers' breadths below the margin of the ribs. The cachexia was at the same time replaced by a certain degree of stoutness.

CASE I.—A labourer, aged forty-three years. was admitted to St. Mary's Hospital on June 3rd, 1896. He had been a soldier for twelve years. He had had good health except for venereal disease, for which he was in hospital. About six weeks previously he first had attacks of shortness of breath, especially at night, obliging him to be propped up in bed or to get up and walk about the room. He has been unable to walk more than fifty yards at a time and had to give up work. Not improving under treatment as an out-patient he came into the hospital on June 3rd; his pulse was 90, irregular, both in force and frequency; the apex beat was in the sixth space half an inch external to the middle line, feeble, fluttering, and diffuse, and there was slight epigastric pulsation. There was a blowing, short, systolic murmur. The other heart sounds were clear, the liver was much enlarged; the dyspnœa was considerable, though nothing abnormal was found in the lungs. With complete rest in bed and digitalis and strychnia he improved to some extent, the liver lessening in size, and he felt quite well in himself, but he was unable to walk even about the ward and the heart was most irregular in action. On July 2nd, after he had been up, the heart was beating faster than it had been. Epigastric pulsation was very marked; the cardiac dulness was increased, and frequently the beats did not reach the wrist. On July 7th

Hosted by Google

I found that at the apex there was a bruit with some beats, but not with all, that the action of the heart was extremely irregular and the breathing very embarrassed by the slightest exertion, and it was more irregular than ever. As no treatment had given much benefit he was ordered mercury and potassic iodide; he began to improve, and by July 21st said he was better than he had been for years. The apex was in the vertical nipple line; the heart above was more regular, though still at times there was an irregularity and systolic murmur, and the pulse was more forcible, but by no means regular The heart condition was a long way off being normal, but he was so well that he would return to work. and he was able to do the heavy work of a crane driver till about Sept. 17th, when he began again to have dyspnœa, but managed his work without much difficulty. On Sept. 23rd he came to see me; his pulse was 108, very irregular in force and frequency; the first sound had a systolic murmur with it at some beats, but not at others, and the action was irregular. I persuaded him to come in again and by Oct. 4th he was very much better, and his pulse was 92 under specific treatment and rest. This case was one of very marked cardiac degeneration of some sort giving dilatation and much dyspnœa; both sides of the heart were certainly dilated. He got much better in a very short time by specific treatment after resisting other methods.

Diffuse fibroid heart-change without dilatation (a) *in the left ventricle.*—In this condition, exemplified by some of the fatal cases in the table, a gradual and progressive loss of power ensues; where the change is limited in extent little is to be found except that the heart's impulse and first sound are weak and there may be some symptoms of cardiac weakness. In advanced cases the action of the heart may get extraordinarily weak, the apex beat becoming imperceptible and the first sound almost or quite inaudible; the pulse is very feeble, irregular, or very rapid or very slow, or alternating between these two conditions; there is a tendency to giddiness, faintness, and syncopal attacks may occur. At times the cardiac symptoms may become overshadowed by those of extreme debility, with inability for any exertion and great loss of energy, sometimes so marked that the patients have to keep their beds; there may be œdema of the feet and there is marked anæmia. Such cases are gradual in development and may go on in this condition for a long time with exacerbations and improvements; they are often put down as fatty heart or as "weak heart," and weak heart they undoubtedly are, but the weakness is due to organic change. These cases unless relieved by treatment die suddenly or from gradual asthenia. Several cases in the table exemplify the fatal results of syphilitic infiltration of the left ventricle without dilatation. Thus in Case 9 in the table "a correct diagnosis was made of a specific cardiac lesion from the peculiar feeble contraction of the heart and the empty arteries, the left ventricle and septum being found post mortem to be the seat of extensive fibroid infiltration creaking on section"; and in Case 19 in the table a man aged forty-five years died suddenly from extensive syphilitic infiltration of the wall of the left ventricle completely destroying the muscular tissue. Case 20 in the table is very similar. When the *right* ventricle becomes fibrotic without becoming dilated the main symptom would appear to be dyspnœa, as in cases where there is dilatation. Probably such disease of the right ventricle alone is not likely to be fatal, but if it involves the septum it may be, as in Case 7 where a man after walking across some fields fell dead in a public house, the necropsy showing extensive fibroid change limited to the right ventricle, septum, and musculi pectinati.

The following appears to be an example of fibroid disease of the heart without dilatation resulting from syphilis.

CASE J.—A man, aged thirty years, came to me at St. Mary's Hospital on Oct. 30th, 1885, complaining of precordial pain of five or six months' duration, with palpitation, dyspnœa (especially after exertion), giddiness, faintness, languor, and aching pains in the knees and shoulders, worst at night; he also had sweats at night. The pulse was 84, of rather high tension; the arteries of the neck throbbed. The apex of the heart was in the fifth interspace, a little inside the nipple line. There was a re-duplicated first sound, which was very weak over the left ventricle, but no bruit. He was treated with digitalis, with strychnia, with both combined, with tonics, and with ergot successively. He got worse rather than better; he could not sleep; his pulse varied from 104 to 112 per minute and was always feeble; he got very haggard-looking and could not resume work though he refused to become an in-patient. In January, 1886, I discovered that a child under my care at Paddington green Children's Hospital for congenital syphilis was his child. On inquiry from him I found that ten years before he had had a chancre. On Jan. 14th I ordered him iodide of potassium and mercury. On the 21st he was "better than he had been all along." The pulse was 100. On Feb. 2nd his heart sounds were much louder and clearer and his symptoms gone. He soon went again to his employment and I wrote to him on Dec. 16th, 1886, and heard from him that he was quite well and living in the country.

The two following fatal cases also exemplify the results of fibroid change in the heart without dilatation. They have not been included in the table, for their nature not being suspected during life enquiry was not made into syphilitic antecedents. From evidence afterwards obtained I believe they were syphilitic. Fagge has shown that fibroid disease from syphilis cannot be distinguished from fibroid disease from other causes even on the post-mortem table, except where there are actual gummata in addition. The symptoms, then, of syphilitic fibrosis are in all probability identical with those of non-syphilitic fibrosis of the heart, and even if these two cases are not of demonstratively proved syphilitic causation they were certainly cases of fibroid disease such as syphilis produces and may be taken as exemplifying the symptoms syphilitic fibrosis may produce.

CASE K.—This patient, a married woman, aged forty eight years, soon after a confinement in 1877 commenced to feel weakness and languor. She came to me in 1884 as an out-patient and on Sept. 3rd, 1884, I took her into the hospital. She complained of pains in the head and attacks of giddiness, during which she had often fallen but without loss of consciousness. She was very short of breath on going up steps and her voice was very weak. There was no dyspnœa when lying down. There was no albuminuria and no impulse of the heart was perceptible and no "first sound" was audible. The pulse was 64 per minute, very weak. She remained in the hospital till Oct. 8th, during which time the first sound of the heart could at times be faintly heard. She preferred to lie in bed always and showed a peculiar languor and want of energy. She occasionally fainted. She was very anæmic and as it was thought she might be suffering from pernicious anæmia the red corpuscles were counted and were found to be about 70 per cent of the normal. She was given arsenic, iron, ergot, digitalis, &c., with little result except that her gums got rather spongy when the arsenic was pushed. Dr. Broadbent kindly saw her with me and agreed that she was suffering from extreme cardiac debility. There was never any rise of temperature and the pulse varied from 60 to 76 a minute. At times she improved and during such temporary improvement went home on Oct. 8th. I went to see her at home at times after this, being interested in the case, and I was informed, in October, 1885, that she had died suddenly in Kensington Infirmary. I made a post-mortem examination, when all the organs were found to be healthy except that the heart was tough and fibrous and the musculi papillares quite rigid and the edges of the mitral cusps were soldered together.

CASE L.—A woman, aged thirty-eight years, who had been married twenty years, came to me at St. Mary's Hospital as an out-patient in February, 1890. She said that she had for a long time suffered from palpitation and faintness. She had had ten children, of whom five had died in infancy. Since the last confinement, in September, 1889, the palpitation had been worse. There was epigastric pain and once she had fallen to the ground in a faint. Her heart action was very feeble and rapid, and as treatment by digitalis and tonics failed to relieve her I sent her into the hospital on April 15th, 1890. She continued to suffer from palpitation, occasional vomiting, and extreme languor; the pulse was extremely feeble, beating often 160 a minute, at other times too fast to be counted; at times the pulse would suddenly become very slow, sinking to 40 a minute, but the heart was then found to be beating 80 a minute, the apex beat was very feeble, but was inside the nipple line, and the heart did not appear to be enlarged; there were no murmurs. Strophanthus appeared at times to relieve her. On June 17th, being a little better, she went to a convalescent home. She returned as an out-patient on July 4th as bad as ever, with swelled feet, slight œdema of the face, marked sallowness of complexion, and a pulse rate of 180. I sent her in-doors again. She then kept her bed, but

Hosted by Google

frequently fainted when she sat up and often became cold and clammy. On one attack on July 18th she was with difficulty revived by stimulants and ether; her face at times flushed up, but she was usually pale; the left leg at times swelled a little; the first heart sound was always very feeble and the second sound often dropped; the action was frequently irregular; usually there was a series of rapid beats with intermission; no diagnosis was made except of cardiac weakness, and digitalis, strophanthus, arsenic, convallaria majalis, and iron were tried without avail. When the hospital was closed for cleaning she was admitted into the Middlesex Hospital, where her husband was a patient with tabes dorsalis. While there a slight systolic murmur was heard and it was noted that digitalis did no good. After being eleven days in the hospital she died in September quite suddenly and unexpectedly when she was thought to be convalescing. At the necropsy there was found a general fibrous myocardial change and œdema of the lungs. For this account of her stay in the Middlesex Hospital I am indebted to the kindness of Dr. Wynter, assistant physician at that hospital.

These two cases illustrate very well the very gradual failure of heart power produced by fibroid heart disease and the languor and weakness to which such patients are reduced, together with the complete failure of cardiac tonics to give relief. During life others besides myself saw the patients and agreed that the one thing that was certain was that there was a condition of extreme cardiac weakness unlike that of fatty disease, and of which the causation was not explainable.

Cases in which there is hypertrophy of the heart.—It will be seen that in several of the fatal cases in the table there was found post mortem considerable hypertrophy of one of the ventricles. In such cases the increased bulk of the heart is produced by fibroid tissue and not by increase of muscular fibre. The diagnosis of such cases rests on the evidences of hypertrophy of the heart without evident cause; where there is no valve disease or albuminuria, and nothing to indicate that the hypertrophy has been set up by great muscular exertion, and where pericardial adhesions are not present, it should be remembered that hypertrophy may result from interstitial fibroses, and this becomes especially probable where the increased bulk of the heart as estimated by the physical signs is not accompanied by evidences of proportionate increase of power. Where the heart-beat is very powerful and the arteries not well filled there is a presumption that the hypertrophy is not a true hypertrophy, and it should be remembered syphilis is a cause of such spurious hypertrophy of the heart. Such cases may terminate fatally quite suddenly, as in Case 5 and Case 16 in the table there was enormous hypertrophy of the left ventricle and an aneurysm near the apex.

CASE M.—A woman, aged fifty-three years, came as an out-patient to St. Mary's Hospital on Oct. 18th, 1886, complaining of palpitation waking her at night, headache, and faint attacks. The pulse was 100 and irregular. The first and second sounds were re-duplicated; the first sound was a little rough, but there was no actual bruit; there was a very forcible heaving impulse over a large area, and the apex itself appeared to be just outside the nipple line. The second sound was loud and clanging. She improved somewhat for a time with digitalis and iron, but at times fainted, and the palpitation continued. In December I noticed a red scar on the chin, and on inquiry found that it resulted from a specific ulceration for which she had attended my colleague, Mr. M. Morris. Her heart symptoms were very soon relieved by mercurial and iodide treatment. Since then they have recurred from time to time and she has frequently come back to me at the hospital and always been relieved by anti-syphilitic treatment. The apex of the heart is in the same position and the impulse forcible, but the symptoms are relieved.

Cardiac aneurysms from syphilitic disease.—The cases in the table showed that in many of the fatal cases aneurysm of the heart-wall had resulted from the syphilitic changes; in some cases death had resulted from rupture of such aneurysms, in others death had occurred from other syphilitic heart lesions. Probably most cardiac aneurysms, when not traumatic, result from syphilitic disease of the heart wall and early recognition of the presence and nature of fibroid cardiac lesions would prevent their formation. In this paper I shall not dwell at more length on these cardiac aneurysms, but the following case, the notes of which have been kindly given me by a military surgeon, is of interest as showing how angina pectoris may be almost the sole evidence of an aneurysm of the heart wall, in this resembling a cardiac gumma (of which it is the later stage) and aneurysm of the aorta at the sinus of Valsalva.

CASE N.—A man, aged twenty-five years, a soldier of seven years' service, was under treatment in 1889 and 1890 for syphilis in a military hospital for 185 days; after that his health was good. He was admitted on Nov. 4th, 1893, into the Station Hospital, Gosport, for indefinite pains in the chest, principally on the right side, whence they extended down the arm. The temperature was normal; there were no physical signs of disease of the respiratory or circulatory organs. On Nov. 5th a severe paroxysm of pain occurred; again on the 6th at 3.30 A.M., and at 8.10 A.M., with vomiting; the extremities became cold, the face pallid, and the pulse imperceptible, and he died in ten minutes. The necropsy showed a small opening concealed by one of the aortic cusps leading into an unruptured aneurysmal sac at the base of the aorta; the wall of the aneurysm was composed of the heart muscle forming a cardiac aneurysm.

DIAGNOSIS.

Of very small gummata in the heart wall, which give no symptoms, the diagnosis is not possible, but they are not of serious importance. Larger gummata in the left ventricle gave rise to physical signs and symptoms. The physical signs are an enfeeblement of the apex beat and the first cardiac sound, or in some cases where the gumma is near the apex evidences of interference with the heart's action, such as abrupt, rapid, apex beat and noisy, short first sound; often the cardiac action is extremely irregular or altered in rhythm. The symptoms are one or more of the following: subjective sensations about the heart, palpitation, giddiness, attacks of faintness or actual syncope, epileptiform attacks, a very rapid or irregular (or perhaps a very slow) pulse, and, above all, anginal seizures. It must be admitted that no one of these physical signs or symptoms—angina excepted—necessarily implies the existence of cardiac disease. Syphilis has been called the "great imitator," and here it imitates gastric or reflex or functional unimportant ailments; and the difficulty in these cases is not so much to decide what form of cardiac disease is present as to decide if there is any heart disease at all. It is not always possible to overcome this difficulty, though it usually is, but I wish to insist on this important fact, that *evidences which we might sometimes set aside as too slight to denote important cardiac disease must not be so set aside in syphilitic persons.* Certainly angina pectoris, with the slight physical signs enumerated above, must be taken as affording strong probability of a gumma in the heart in syphilitic persons, even without another symptom. Of the other symptoms named no one individually is pathognomonic of organic heart disease, but if there be more than one of them—e.g., syncope and palpitation—with the slight characteristic physical signs, there is a similar probability in syphilitic persons. Gumma of the *right* heart may be suspected from dyspnœa unaccounted for by left heart disease or lung disease or dilatation of the heart when with it there is the slightest evidence of right heart difficulty in syphilitic persons. One factor influencing the diagnosis in all cases will be the evidences of previous syphilitic infection and the results of specific as compared with those of non-specific treatment; such evidence is always regarded as important in disease of other parts of the body, and we are not more or less dependent upon it in the diagnosis of cardiac syphilis than we are in the diagnosis of visceral syphilis in general.

Diagnosis of dilatation of the heart from syphilitic disease of the heart wall.—Inquiry into the previous history, the habits, and the general condition of the patient is required in determining whether any dilatation of the heart from which he is suffering is attributable to syphilitic disease of the heart wall. If the left ventricle is found to be dilated without valvular disease, nephritis, or other causes, which produce increased strain upon the heart fibre, it may be concluded that the dilatation is due to parietal weakness. Of the conditions producing such weakness fatty degeneration may be for the most part excluded, for it rarely gives rise to dilatation; but if it is suspected the age of the patient and the usual data which guide us in the recognition of fatty disease must be appealed to. Apart from fatty disease debility of heart fibre can only be due to myocarditis in some form; and if there be no history of acute fever or illness, and there is not present any cachectic state to weaken the heart-muscle, the myocardial change is in all probability a fibrous one; this becomes still more probable if no improvement results from the usual cardiac tonics; and if

Hosted by Google

the patient has a history or traces of syphilis, and specific treatment succeeds where digitalis, &c., has failed, there remains very little doubt that the dilatation of the ventricle is the result of syphilitic fibrosis. In certain cases of syphilis the patient becomes cachectic, anæmic, and feeble, with or without pyrexia, and some dilatation of the heart may occur as a result of the general condition. Without any fibroid heart lesion the dilatation and general condition improve together in these cases under anti-syphilitic treatment, but they are readily distinguishable from cases in which, the general health being good, there is dilatation from syphilitic disease of the heart wall. Dilatation of the *right* ventricle from fibroid heart disease is, perhaps, more difficult of detection than of left heart dilatation. This, however, it has in common with dilatation of the right heart from other causes. But that dyspnœa is produced by dilatation of the right heart from fibroid disease and that it is a very constant symptom in such cases is proved by the history and post-mortem appearances in many of the cases in the table; and in syphilitic persons persistent or paroxysmal attacks of dyspnœa without obvious cause, and even with but slight signs of right heart enlargement, should be looked on as possibly resulting from fibroid change.

Diagnosis of diffuse fibroid syphilitic disease of the heart-wall without dilatation.—When the fibroid change is of limited extent, though not forming a gummatous nodule, the only symptoms will be those such as are producible by gummata; in such cases the probability of the heart weakness being due to syphilitic fibroid changes must be adjudged upon by taking into consideration the age of the patient, the results of inquiry into possible syphilitic infection, and the effects of the ordinary cardiac tonics as compared with those of specific treatment. A due consideration of these will in many cases enable the cases of heart weakness from syphilis to be distinguished from those resulting from other causes.

When the fibroid change on the left ventricle is widespread, involving, perhaps, the musculi papillares as well as the ventricle wall, the cardiac debility gradually increases till it becomes extreme and the diagnosis is not difficult; indeed, it is much more readily made than in those cases where dilatation is present, for while many causes produce cardiac weakness with dilatation the causes of great cardiac weakness without it are few—in fact, only fatty disease; but this can only produce such extreme heart weakness as widespread fibrosis causes when present in an extreme degree, and then, as Walshe[10] points out, "its clinical evidences are more or less precise and positive." In addition, the age of the patient and the previous history will often enable us to distinguish between the two conditions. The course, too, of fibroid disease is very different from that of fatty degeneration, for when the latter has once reached such a point as to produce syncopal attacks, and irregular or almost imperceptible pulse, death ensues, whereas in fibroid disease patients may suffer from cardiac weakness sufficient to prevent their moving about and to suffer from a languor and apathy they cannot overcome and to keep them almost to confinement in bed and yet go on for months in much the same state. The distinction between diffuse fibrosis and fatty degeneration of the heart is not usually difficult. (This was evidenced in the two cases K and L, in both of whom it was agreed by those who saw them that there was extreme cardiac debility, but that it was not due to fatty degeneration.) These cases of general fibroid disease of the left ventricle without dilatation may be diagnosed when in persons mostly in mid-life sometimes later on there occur manifestations of a very chronic, gradually increasing cardiac weakness, with an extremely feeble pulse, sometimes very rapid and sometimes suddenly becoming slow, with tendency to syncope and an extreme general feeling of weakness, and with increasing languor and apathy. These cases do not improve under cardiac tonics, though they may temporarily give promise of improvement, especially under strophanthus.

Treatment of syphilitic disease of the heart wall.—This is the same as of syphilis of other internal organs.

CONCLUSION.

1. Syphilis may produce gummata or general fibroid change. 2. Gummata in the left ventricle, except of very small size, are dangerous to life, and when near the apex of the left ventricle may cause sudden death. 3. Gummata in the left ventricle may be suspected if, in an individual with syphilitic antecedents there occur signs of derangement of the action of the left ventricle with symptoms of defective or embarrassed action, especially angina pectoris, tachycardia, syncopal or epileptiform attacks, or in the right ventricle when dyspnœa otherwise unaccountable occurs. 4. Extreme feebleness of the heart without dilatation gradually increasing in young or middle-aged persons who have had syphilis suggests syphilitic disease of the left side of the heart, and long-standing dypsnœa may point to similar disease on the right side of the heart. 5. Dilatation of either side of the heart in syphilitic persons may result from syphilitic fibrosis. 6. Hypertrophy of the heart without ascertainable cause and without corresponding increase in strength of heart suggests syphilis. 7. Aneurysm of the heart wall may result from syphilitic local lesions and may be fatal with or without rupturing. 8. It is probable that gummata and fibroid disease in early stages may be relieved or cured by the usual specific treatment, and there is every reason to believe that syphilitic lesions of the heart wall are not less amenable to treatment in their early stages than syphilitic lesions elsewhere, though no cure can be expected where advanced tissue changes are already produced. In what I have written I have devoted attention only to syphilitic disease of the heart wall apart from valve disease. It is certain that the small number of cases I have given in the table (and I might have added many more) must represent a much larger number of unrecorded fatal cases—cases in which no necropsy was performed or the fibroid condition was not recognised or reported, and a very greatly larger number of cases of persons who have suffered from syphilitic heart lesions without their producing death. It is, therefore, certain that syphilitic heart disease is more common than is generally recognised. And its importance is the greater because it affects persons at an earlier age that the usual degenerative heart conditions and may insidiously advance till it causes sudden death in persons in the prime of life and of apparent health.

There can be little doubt that syphilitic heart affections must affect the administration of anæsthetics, more especially as a life-long disease like syphilis is apt to produce local conditions that require operative interference not infrequently. Certainly cases are brought in of death under an anæsthetic from fatty disease of the heart in which the chief evidence of that condition is that the patient died under anæsthetic, and at the moment I write a case[11] is recorded of death under the administration of the A.C.E. mixture in which "the right ventricle was found dilated with fatty infiltration of its walls; the left ventricle was also dilated and there was some fibrosis of its walls." Dr. Kirk[12] found that chloroform, if we may judge from a few cases, is liable to give dangerous results in syphilitic subjects.

[10] Diseases of the Heart, p. 338.

THE REMOVAL OF SUPPURATING PELVIC TUMOURS: ILLUSTRATED BY TWO CASES.

BY ALBAN DORAN, F.R.C.S. ENG.,
SURGEON TO THE SAMARITAN FREE HOSPITAL.

THE two cases which are related in this communication offer certain instructive features in common. In both the structures which were removed contained pus, and in both the tissues of the pedicle were unhealthy, not from infiltration of any new growth, but from inflammatory changes. Both patients were restored to health, but the details of treatment involve matter for comment. The chief subjects worth consideration are the management of unhealthy pedicles, washing out, and drainage.

CASE 1.—On March 8th, 1894, my friend Dr. Ilott of Bromley consulted me about a girl aged sixteen years who had been under his care for six weeks. She was thin, but had been fairly healthy till the present illness. When Dr. Ilott first saw her she showed symptoms of peritonitis an

[11] Brit. Med. Jour., Feb. 3rd, 1895.
[12] Ibid., Dec. 12th, 1896, p. 1706.

Hosted by Google

effusion into the left pleura. A few days later there was evidence of free fluid in the peritoneum, the temperature reaching 104° F. Under appropriate treatment all the acute symptoms subsided; then a hypogastric tumour was detected. The periods had been absent for five months. When I first saw the patient the abdomen was almost flat, excepting below, where a swelling rose above the pubes, reaching half-way to the umbilicus. It fluctuated obscurely and was but slightly moveable. The cervix lay high up close to the pubes, the sound passing two and a half inches upwards and forwards. The tumour, which moved with the uterus, dipped deeply into Douglas's pouch and seemed to be closely related to the posterior part of the cervix. Diagnosis in a case with the above symptoms was difficult, though I suspected either a tuberculous abscess or a suppurating dermoid cyst, the clinical evidence of a low form of inflammation being strong. Sarcoma was improbable, though malignant ovarian growths are proportionately frequent in girlhood and are generally accompanied by amenorrhœa. They grow rapidly and seldom suppurate, whilst in Dr. Ilott's patient inflammatory changes had appeared before the tumour had reached a high stage of development. Menstruation often ceases from any cause of debility, and examination of the uterus showed that pregnancy was out of the question. I operated on March 18th, assisted by Dr. Ilott and Mr. Yolland. The abdominal incision exposed a dull greenish tumour adherent to the parietes and thickened omentum and intestine. Above the tumour the peritoneum and bowels seemed to be healthy, so I protected them with a flat sponge. On puncturing the tumour pus mixed with yellow grease escaped and a few hairs were seen. I injected iodine water into the cavity of the suppurating dermoid ovarian cyst, for such the tumour clearly was, a tooth being discovered as well as hairs. Then I detached the cyst from very intimate adhesions. It lay in a kind of capsule, practically the wall of an abscess. The left tube, obstructed and dropsical, ran over on the surface of the cyst. I succeeded in finding a true pedicle, after detaching the tumour from the back of the uterus. The tissues of the pedicle seemed to be involved in the suppurative process. Having ligatured the ovarian vessels, I transfixed the pedicle and tied it with No. 4 silk, cutting away the tumour. The right appendages were bound down by adhesions, but being otherwise sound I did not remove them. The result showed that this step was right. I simply liberated the ovary and tube from adhesions. As some of the contents of the cyst had escaped into the general peritoneal cavity I thought it right to flush the peritoneum at once with hot water, repeating the process before closing the abdominal wound. Lastly a drainage-tube was passed into Douglas's pouch. Much trouble followed, owing to the condition of the pedicle. After removal of the drainage-tube a few days after the operation I syringed out the cavity with antiseptics. On the fifth day the ligature came away as well as the No. 2 silk with which I had tied the vessels in the outer border. In spite of all precautions there was suppuration of the subcutaneous tissues, preventing primary union of the skin, though the muscular layers united firmly. After discharge of the ligatures the wound began to heal rapidly, the cavity filling up. On May 5th the period returned after an absence of nearly seven months. Dr. Ilott wrote to me in March, 1896, two years after the operation, saying that "the patient is in excellent health, quite plump and strong. There is no yielding of the cicatrix, nor pain at the site of operation. The period is quite regular every month; it is rather scanty, and lasts about three days."

The following case is an instructive example of very chronic inflammatory disease of the appendages.

CASE 2.—In 1886 Mr. Kingston Barton of South Kensington asked me to see in consultation a young married woman then aged nineteen years. She had suffered from acute pelvic pain since a recent miscarriage. I found the right appendages enlarged and tender, but quite moveable, and agreed with Mr. Barton that no operation was justifiable. Under his care the painful symptoms disappeared. The patient married for the second time early in 1890. A few months later she caught a severe chill through travelling by train in damp boots. Pelvic pains occurred and the periods ceased. I examined her in June of that year and found that she was pregnant. I could not detect any inflammatory deposit in the pelvis, but pelvic exploration is difficult in a pregnant subject. Dr. Clapham of Wimbledon attended her when she was confined at term. The child yet lives. In 1893 she bore another healthy child. Severe abdominal pains set in three months later. Dr. Sheppard of Putney kept her in bed for fourteen days. The pain passed away. In 1894 she had measles for the first time in her life. Acute inflammation of the ovary followed. Under the treatment of Mr. Pedler of Knightsbridge her health improved, but she did not rest sufficiently to ensure perfect cure. In February, 1895, a violent attack of pelvic pain occurred at the period, with a great rise of temperature. The patient was now twenty-eight years of age and well nourished, but her face was deeply flushed. I examined her early in April. A soft, tender, fluctuating tumour could be felt in each iliac fossa, the right being the larger. The uterus was three inches long and moveable; the swellings extended low down in the corresponding fornices. The pulse was 144, and the evening temperature 100·6° F. A few days later it rose to 102·8°, and the period appeared. I wished to explore directly it ceased, but was prevented from doing so by several complications. On April 17th one eye became inflamed. Mr. Lindsay Johnson examined her and diagnosed keratitis of bacterial origin. It subsided, but the pelvic condition did not improve. On May 8th the pain was very severe. The swelling in the left iliac fossa was tense and pressed down on the rectum. As I particularly wished to avoid any fistulous tracks communicating with the intestine I tapped the swelling through the vagina, withdrawing about five ounces of pus. The period appeared on May 10th. The patient, who had been kept in bed since April 8th, was now in a more favourable state of health, but the swellings began to increase in size. On May 18th I operated, with the assistance of Dr. Hubert Roberts. An incision three inches long was made in the middle line and was found to be quite sufficient for the subsequent manœuvres. The first thing visible when the peritoneum was divided was the right swelling, a big cyst, which I tapped with a long trocar and cannula. Pus came away; then I used an aspirator, removing a pint of very thick yellow pus free from odour. I protected the parts near the cyst by placing iodoform gauze around the point selected for puncture. By this procedure, repeated on the left side, not a drop of pus strayed into the peritoneum. I washed out the cavity of the cyst with iodine water. Then I separated the cyst from universal surrounding adhesions. It was the right tube converted into a thick-walled abscess and extremely dilated. The ovary was broken to pieces during extraction. I secured the ovarian vessels with No. 3 silk and then transfixed the pedicle and tied it with No. 4 silk. The tissues were infiltrated with inflammatory deposit, but not suppurating. The pedicle was then divided. I touched the raw surface with tincture of iodine, after carefully trimming away with scissors the exposed part of the tubal mucous membrane. On the left I found a similar morbid condition. The omentum was thickened and otherwise unhealthy, so I ligatured and divided it high up, far above the left cyst to which it was strongly adherent. I was much relieved to find after tapping and injecting with iodine that the cyst wall could be detached from the vagina and rectum without damage to either. The pus, owing to the tapping, I presume, was slightly sour. After securing and dividing the pedicle, as on the right side, I washed out the pelvis with iodine water, placed a sponge in Douglas's pouch, and introduced the sutures. As there was no evidence of oozing when I drew up the sponge, and since I felt persuaded that no pus had escaped into the peritoneal cavity I closed the wound. I wished to avoid the evil effects of suppuration of the pedicle and coming away of the ligatures. The drainage-tube is apt to promote that complication. Since the pedicles were not actually suppurating, as in the first case, I considered that closure of the wound was the best way to ensure speedy recovery. Fortunately the patient was spared the annoyance which was probably inevitable in the former case, where the pedicle was already suppurating when it was secured by ligature. Convalescence was protracted, owing to a second attack of keratitis beginning on June 20th. By the end of the month, however, the patient was well. I saw her in December, 1896, when she was in excellent health. The periods had been regular since August, 1895.

There are certain special considerations relating to each of these cases. In the first the right appendages were saved after being freed from the adhesions which bound them down. They showed no signs of disease save what was due to the peritonitis around them, and when liberated they were restored to their functions. The catamenia have returned and the patient is capable of bearing children. Thus the removal of the right appendix would have been wrong. Even in chronic pelvic disease in much older subjects,

Hosted by Google

when one tube and ovary have been hopelessly damaged, their fellows may sometimes be spared after liberation from adhesions which keep them bound down low in the pelvis, interfere with their blood-supply, and impede their functions. On the other hand, when, as in the second case, bilateral pyosalpinx is evident, both appendages must be removed, else the operation will be useless and its danger much increased. In the first case the suppuration was unilateral, being confined to the dermoid cyst of the left ovary and its pedicle.

The most remarkable feature in the second case was the long duration of pelvic disease. I observed it nine years before operation. Four years after its first appearance and subsidence it was lit up afresh by a chill. The same phenomenon is familiar to all in cases of dental caries. Yet the patient conceived and bore two children. Four years after the chill, acute exanthematous oöphoritis occurred—a well-established disease. The inflammatory changes extended to the tubes, and the parts through want of care at length became irremediably diseased. The tumours full of pus were the tubes, each bent on itself at a very acute angle, and not suppurating tubo-ovarian cysts. The frequent error of mistaking the latter for the former and overlooking the ovary, often small and adherent to the outer side of the cyst, can be avoided by a little pathological knowledge. The surgeon must ever be sceptical about reported "ovarian abscess."

Of the three general considerations suggested by these two cases unhealthy pedicle must be considered first. In an uncomplicated ovariotomy the pedicle of the cyst is quite healthy, its tissues being free from inflammatory deposit. The tube bears a sound mucous membrane. Experience shows that the ligature is well tolerated in such a case. The changes undergone after the operation are well known. Conditions are from the first clearly in favour of such a pedicle. When, on the other hand, inflammatory processes are in progress in any of its elements the case becomes complicated. The ligatures will lie amongst tissues that will not readily tolerate their presence. The process by which the distal part of the stump is preserved is unfavourably modified when the tissues of the pedicle are infiltrated. A good deep groove with the bulging structures on each side of the ligature accurately in contact with each other is not so easily made as when the parts are healthy. Nevertheless, an inflamed pedicle of a common multilocular cyst rarely gives trouble after operation. The tissues in the stump are placed in a better position for recovery from inflammation. The cutting drains it, and its large vessels, no longer employed in carrying blood to and from a big tumour, close up. The stump shrinks up, though, no doubt, not so quickly as when free from morbid changes, and ultimately passes through the salutary processes which begin earlier in a pedicle healthy from the first.

The case is much less favourable when the inflamed pedicle is connected with a small structure also inflamed, such as a small dermoid or a suppurating tube or ovary. There is much less of that salutary shrinking which takes place when a large pedicle full of engorged vessels is severed from a big tumour. The distal part of the stump is not so early or so readily supplied with nutrition, as the groove is not easily made deep enough when the ligature is tied, nor do the tissues bulge and touch each other so readily, nor does the proximal side so speedily throw out nutritive lymph to save the distal structures. Disease of the tubal mucous membrane is a yet graver complication. Without precautions a patient may feel worse after the removal of diseased appendages than before. The ligature may ultimately lie in an abscess cavity or the stump may develop into a hard, painful, inflamed mass, more or less strongly adherent to adjacent structures. In the first case the pedicle was already suppurating. I was obliged, of course, to secure it with a ligature. The silks came away within a few days. The relation of the management of a pedicle in this condition to drainage is self-evident, so this subject will again be considered further on. In the second case there was no evidence that the suppuration had extended beyond the tubes. The pedicles bore the ligatures well. As there was a pyosalpinx on each side I took care to trim away the mucous membrane of the tube, as it bulged from the cut surface of each pedicle, and to touch the exposed tubal coats with tincture of iodine. Thus was avoided as much as possible the danger of leaving a focus of suppuration in each fornix. When, therefore, a pedicle is actually suppurating it must be ligatured in order to prevent hæmorrhage. In every other respect the ligature is absolutely pernicious. The pelvis must be drained to allow of the escape of fragments of suppurating tissue; the silks will possibly come away within a few days. More often the stump becomes healthy and tolerates the ligature after a time. When the tissues of the broad ligament are inflamed, yet the suppuration is limited to the tube, a ligature may be safely applied and the abdominal wound closed, provided that the exposed tubal mucous membrane be trimmed and the stump of the tube disinfected.

Washing out the peritoneal cavity is necessary after the removal of a large abdominal tumour, where numerous vascular adhesions have been separated, or where blood or the contents of cysts have been scattered about in uncertain directions. This practice is a true process of flushing, by which alone can noxious material be thoroughly dislodged from distant recesses of the abdomen. When an inflamed pelvic tumour or a suppurating tube has been carefully removed, and the operator feels sure that he has prevented the escape of any of its contents into the peritoneum, flushing is not only needless, but it is dangerous. Infection is thereby promoted rather than prevented. In the first case I was obliged to flush out the general peritoneal cavity, since I knew that pus had actually escaped upwards. I regretted having to take that step, but I could not, of course, trust to the disinfecting of the interior of the cyst by the injection of iodine water earlier in the operation. In the second case no pus was allowed to escape into the peritoneal cavity and flushing would have been, in my opinion, criminal. It would simply have carried septic material upwards. The washing out of the pelvis with hot iodine water—true irrigation—counteracted shock and stopped capillary oozing in Douglas's pouch, a grave promoter of sepsis. The iodine was added because an antiseptic was demanded. Drainage was clearly indicated in the first case. I could not have closed in a cavity lined with suppurating granulations deposited on adjacent intestine and peritoneum. Besides, to shut up a suppurating pedicle in the peritoneum would have been bad surgery. The tube was removed within a few days, for there is danger of perforation of the rectum in these unhealthy cases if the tube be kept in too long. The cavity was afterwards syringed out with antiseptics till it closed. The ligature came away, but that accident involved no trouble, and the patient has been free from pain ever since the operation. It must not be forgotten that needless drainage promotes morbid changes around the ligature. Hence I did not use the drainage-tube in the second case, where there was no evidence that the suppuration had extended outside the cystic tubes and the vaginal puncture had closed. In short, when a suppurating pelvic tumour is removed drainage is necessary if any suppurating structures are left behind; but if not, then, other conditions being favourable, the drainage-tube will not be needed.

VITALITY.

By LIONEL S. BEALE, M.B., F.R.C.P. LOND., F.R.S.,
EMERITUS PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE IN KING'S COLLEGE, LONDON, AND CONSULTING PHYSICIAN TO THE HOSPITAL; GOVERNMENT MEDICAL REFEREE FOR ENGLAND.

VI.[1]—VITAL CHANGES IN NERVE TEXTURES (*continued*).

IN the very elaborate structures taking part in special sense and in mental action, as well as in various tissues and organs, the substance, the actual matter upon which origin, development, growth, formation, and action depend, is in a living state. This living matter is invariably found to contain a very large proportion of water, a condition which must permit the very free movement of the particles amongst one another. These movements characterise all forms of living matter and are more active when living matter is in a state of great activity. All the remarkable properties of various tissues and at every period of life depend upon the powers of the living matter from which they originated. The living matter alone renders possible increase and growth in early life, maintenance when fully formed, including the

[1] Nos. I., II., III., IV., and V. were published in THE LANCET of Feb. 22nd, April 11th, June 13th, Aug. 29th, and Oct. 17th, 1896, respectively.

Hosted by Google

replacement of the matter which is used up during action while life lasts, and repair in case of injury. By the death of structureless living matter all further normal action is rendered impossible, though wonderful structural arrangements already produced may be intact, readily demonstrable in very minute details, and capable of being indefinitely preserved in many cases. Of all our organs, those concerned in hearing and sight are probably the most complex and elaborate in their minute structure and most remarkable as regards responsive activity. The many different structures with their different properties present in these organs work together in perfect harmony, but the actual particles engaged are so very minute that their form, arrangement, and relations to one another and to tissues has not yet been satisfactorily demonstrated. Organs of sight and hearing and other sense organs of some classes, though appearing to be mainly composed of rigid, hard, and almost dry textures, perhaps differing widely in structure, agree in this—that the active power is invariably due to the presence of matter in a living state, which is always moist.

All the efforts—and they have been many—to discover analogies between the almost perfect organs of living things and the scarcely less striking pieces of apparatus designed and constructed by man for the transformation of energy have signally failed. That such comparisons should have been attempted by anyone who had even but very imperfectly studied the special structure and arrangement of the apparatus in both cases and was acquainted with the general phenomena occurring during action, to say nothing of their so-called evolution, is, indeed, remarkable, seeing the utter want of resemblance in appearance, composition, arrangement of parts, origin, and action between the natural organs and the constructed apparatus. Take, for example, the electric organ of a living organism and any form of of electric apparatus made by man.

The difficulty of making out the exact arrangement of the various anatomical elements, and their precise action in many of the sense organs, even amongst the lowest organisms, is so great that we are still unable to form an accurate idea of their action, and particularly in the class of insects are the arrangements on a scale so minute that it is not possible to clearly demonstrate the details with the highest magnifying powers. And in these cases in which the general arrangement has been demonstrated, the manner in which, say, in a light-emitting organ, the transformation of energy is effected, has not been determined. But there can be little doubt that the matter actually engaged in effecting the re-arrangement of the constituent elements concerned in the process is in the living state. The power by which all the movements and arrangement of the atoms are directed and regulated is vital power, which power, as I have shown, must be placed in a category by itself, being entirely distinct from all known agencies and forces which operate in the non-living world.

No essential points in common between any living form and any non-living mechanism constructed by man have been pointed out, although some distinguished men of science have stated that in certain cases the manufactured apparatus has been more free from defects and more perfect in its action than the natural structure formed from the structureless living matter according to processes which have been in unceasing operation through countless generations in past ages. To adversely criticise, for instance, some parts of the visual apparatus without taking into consideration the fact that every part concerned in sight has somehow during its formation in darkness adapted itself, or has been adapted, for use under varying conditions of distance, light, colour, and the nature of the surrounding medium is surely neither fair nor reasonable. No artificial optical arrangements yet made exhibit any such power of adaptation. Moreover, the latter are for the most part but aids to ordinary natural vision and are useless in the absence of the eye, as well as destitute of any means of being properly focussed without the aid of the hand acting in conjunction with the eye. Nor could they have been constructed without eye and hand and the peculiar endowments of these organs transmitted through countless generations of human beings. How, then, is it possible to compare the eye of a living organism with an optical instrument which is but an artificial aid to the eye in certain cases, and which is made and adapted to suit the natural organ? Nor must we omit to bear in mind that, unlike any optical instrument, the eye comprehends many complex and delicate structures, which differ somewhat in structure and arrangement in the different types of eye. In every case the formation of these tissues was prepared for, and their development commenced, long before any indication of the characters and action to be ultimately attained could be discovered, each one being developed according to a predetermined plan or design and prepared for in the absence of light. Nor are the several tissues, which when fully formed work together in harmony, all developed at a uniform rate or in the same periods of time. Are we not, then, compelled to admit the existence of a peculiar governing guiding power—of a nature quite distinct from any agencies or properties known in connexion with the non-living world? Is it conceivable that in consequence of any advance of our knowledge concerning the non-living, the production of these wonderful structures and their relations to one another will be explained by physics or that they will ever be produced artificially? They all grow out of, and are formed from, the structureless, which has been produced by—has descended from, pre-existing structureless, and in this way only.

Considering, then, that in nature there are several kinds of organs designed and constructed to discharge corresponding offices and also adapted to the particular conditions under which their possessors live, each kind having special powers of its own and working under different conditions as regards temperature, pressure, light, and kinds of foods,—considering that every peculiarity and every variation in structure is due to inheritance from previously existing organisms, and that corresponding tissues and organs are perfected in very different periods of time, at different temperatures, formed from different kinds of food, retaining their activity in some instances for many years, in others for months, weeks, days, or even hours only, is it not unreasonable, at any rate until we learn more than is yet known concerning the actual phenomena proceeding during their formation, to suggest that the time will come when corresponding organs, or any apparatus performing like functions, will be constructed by man?

The living matter from which, through the agency of its wonderful vital endowments, all tissues proceed seems to be composed of comparatively few elements, the properties of which, so far as investigation has yet gone, afford no explanation or clue to the nature of the powers at work or of the exact way in which the results are attained, much less of the series of changes which occur as the positions of the elements with respect to one another become altered and take up new relations, necessitating the production of the particular substances with their special properties predetermined from the first, often in darkness, or at least under circumstances from which the access of all ordinary light rays is excluded.

No differences in chemical composition or in molecular constitution as yet discovered in any form of living matter will account for the production of any tissues or organs. Nor is it in the least degree probable that differences in vital power, upon which the formation of every form of structure and the discharge of function depend, will ever receive an adequate physical explanation. Nothing is known in connexion with the action of any sense organ or any kind of nerve action which would justify the conclusion that ultimately it will be shown that these are consequent upon any form of change not directed and governed by vital action. Why, for instance, the hard matter of some cuticular structures should be produced by one kind of living matter, soft mucus by another, bile by a third, nerve current by a fourth, and so on, has not yet been explained. It is certain that these several forms of living matter, which give rise to the production of such different substances and effects, have all been derived by descent from a form of living matter which did not possess the power of any one of them or any of the several formative powers at length manifested by its descendants. Nor can any one of these differences in power be shown to be due to the influence of external agencies or conditions acting upon them. It seems to me that to vital power temporarily associated with the matter of the living particles and capable of directly acting upon their elements and of altering their relations to one another must be attributed the general and special characteristic activities manifested. The wonderful movements and the re-arrangement and alteration of position and relation with respect to one another of the component elements of every known kind of living matter must, I think, be referred to the exercise of this power alone. And though it may be said that we only assume the existence of vital

Hosted by Google

power in causing the changes which ensue in the matter supposed to be under its sway, it is certain that no phenomena at all comparable with those which characterise every particle of matter that lives, whether it be high or low, simple or complex, have been manifested by any form or state of matter which is not living.

All attempts to show that life, vitality, in any living particle, is capable under any circumstances of being converted into, or made to take the form of, heat, light, electricity, or other form or mode of motion have so far signally failed. Indeed, the manifestation of various forms or modes of energy in living things appears to be a direct result of a certain rearrangement of the atoms of living matter, the rearrangement being effected by the operation of vital power upon the material particles with which it is temporarily associated. The change in position and relation of the atoms is no doubt accompanied, though not caused, by chemical action, and in many cases by the evolution of heat, light, or electricity. In the present state of our knowledge, as it seems to me, this is the nearest approach to an explanation that, in strict accord with known facts and reason, can be advanced, and, indeed, the only way in which the rearrangement of the particles, which undoubtedly takes place, can be accounted for.[2]

I submit, then, that so far all the facts adduced and the arguments founded upon them establish the conclusion that the living matter which is directly concerned in the development and formation of the most complex and highest organism, organ, or tissue, be it vegetable or animal—man, an eye or a brain cell—exhibits no special characteristic which would enable us to decide what particular organism, organ, or tissue was about to be produced, or to distinguish it from living matter from which some low and comparatively simple organism, organ, or tissue of the most passive and unchanging kind would be evolved. The results of the influence of life power on matter cannot, in fact, be foreseen. The results may be observed and the resulting structures subjected to investigation, but the power itself is not demonstrable and cannot be isolated. It stands by itself among natural agencies. Its origin is unknown and the means by which it is communicated to non-living particles undiscovered and perhaps undiscoverable. That vital power is transferred without loss is quite certain. Nothing is added to the weight of the matter when it becomes living—nothing taken from it when it ceases to live. Vital power in many cases undergoes certain modification as regards its special characters, probably at a time when it is least active and perhaps at a time when it appears to be in a dormant state, the modification in power being evidenced in the departure from the characters, properties, and action of the tissues and organs formed.

I claim, then, vital power—vitality—as the agency upon which the composition, characters, minute structure, and action of all tissues and organs in every living organism directly depend. In the absence of vital power not a structure characteristic of any living form in nature could have existed. It is the wonderful operation of vital power which distinguishes all living from all non-living. Vital power effects the separation from one another of elements in combination in the various substances which constitute the pabulum of the living, rearranges these elements, and determines their new position, so that new combinations resulting in the formation of particular compounds are occasioned. Such analytical and synthetical operations are of a special kind and are always proceeding, slowly or quickly, in every particle that lives, and many of the products as regards properties, composition, and action—predetermined, as it were foreseen—are inimitable and obtainable only from organisms in a living state or that have lived.

These general conclusions will be further strengthened by observations which will be advanced in the next communication, "On the Interstitial Circulation of Living Organisms in Health and Disease."

(To be continued.)

[2] Seeing that energy is indestructible, while life—vitality—ceases without undergoing conversion into any form or mode of motion, and cannot, therefore, be indestructible in the same sense as that in which matter and energy are held to be indestructible. It cannot, however, be said to be impossible that some life may be destructible and some indestructible, but in this case the supposed destructibility or indestructibility must be due to a potency which can be perpetually multiplied without any addition to, or change of, or subtraction from, any material forces or properties associated with the particles concerned.

THE ACTIVE PRINCIPLE OF INDIAN HEMP: A PRELIMINARY COMMUNICATION.[1]

BY C. R. MARSHALL, M.B. VICT.,
ASSISTANT TO THE DOWNING PROFESSOR OF MEDICINE IN THE UNIVERSITY OF CAMBRIDGE.

Introduction.—The want of uniformity in the preparations of Indian hemp has so often led to serious consequences in practice that many practitioners have discarded the drug as worthless or dangerous. Others, finding it of benefit in certain diseases, have expressed a hope that some means of standardising it would be discovered or the active principle of the plant isolated. Of the two conditions, the isolation of the active ingredient is the more important and its use is more likely to lead to uniform results in treatment. Quite recently such a pure active product has been obtained and the mystery which has hitherto enveloped Indian hemp seems in a fair way to being cleared up. Many points still need investigation, the most important from a medical point of view being the gradual change which cannabis compounds undergo by keeping. Both by practical experience and scientific experiment it has been shown that the active ingredient gradually loses its power, and at present we know of no means of preventing this. A very interesting case of this loss of activity is described by Thomas Smith.[2] He found that cannabin, which, when freshly prepared, produced a narcotic effect in doses of two-thirds of a grain, after exposure to the air for three years became absolutely inert.[3] In India, it is said, dealers in this drug refuse to buy the old crops after the new ones are gathered, and after two years the crops are publicly burnt in the presence of an Excise officer. The cause of this growing inertness is probably due, as Leib Lapin[4] suggests, to the oxidation of the active ingredient. He mentions experiments in support of this view, but these are not sufficiently convincing. Age, however, will not account in all cases for the uncertainty of commercial preparations. More often it is due to the more or less inert natural products from which these preparations are made. That the physiological activity of the hemp plant varies with the locality in which it is grown is well known, and it has been suggested that the gánjá of Bombay and the Central Provinces, which is "infinitely inferior" to that of Bengal, finds its way into European pharmacy. "There is also good reason to believe that the Indian hemp merchants, who deal with the drug in the first instance as an article of excise consumed locally, are in the habit of supplying to the European drug exporter or his agents samples for which, owing to the partial or complete loss of activity, they can no longer find a native market."[5]

Natural products.—The principal natural products obtained in India from the hemp plant, excluding the fibre, oil, and seed, are known as charas, gánjá, and bháng.[6] *Charas* is a resinous exudation found on the leaves, young twigs, immature fruits, and bark of the stem, and is regarded, and with justice, as the most active preparation of the hemp plant. It is gathered by rubbing the flower-tops between the hands, or by men, naked or wearing leather coats or skins, running through the fields; it is then scraped off and made

[1] Suggested by Dr. Walker's letter in the British Medical Journal of Nov. 7th, 1896, p. 1382. The experimental part of this communication was read before the Cambridge Philosophical Society on April 19th, see their Transactions, vol. ix., part iii., p. 149.

[2] Pharmaceutical Journal [3], vol. xv., p. 853.

[3] O'Shaughnessy also found that the extract which he himself brought from India did not produce in England the effects which he anticipated (Pharmaceutical Journal, vol. vi., p. 71). This may have been due, in part at least, to the age of the preparation. Christison (Watt's Dictionary of the Economic Products of India, vol. ii., p. 123), on the other hand, states that he used for some years an alcoholic extract sent to him from Calcutta twenty years before, and which was still as powerful as ever to relieve pain and obtain sleep. Casiccia (Rivista di Chimie, Medicina e Farmacologia, July, 1883, p. 326; Virchow's Jahresberichte, 1883, Band i., p. 438) also quotes a case of poisoning with 2 grammes (30 gr.) of a very old extract.

[6] This account has been compiled from Watt's Dictionary of the Economic Products of India, vol. ii., p. 113 et seq., to which the reader is referred for further information, and from a private letter from my friend Mr. John Stephenson, I.M.S. A good account is also given in Flückiger and Hanbury's Pharmacographia, p. 493.

Hosted by Google

into cakes or pills. Most of the substance is prepared in Kashmir and is imported into Northern India (the Punjab principally and the North-West Provinces) from there. It varies considerably in activity, being adulterated to a great extent with powdered leaves and other substances. *Gánjá* is composed of the "female flowering tops with the resinous exudation on them." After gathering, these are exposed to the heat of the sun and then left over-night to the influence of the dew; afterwards they are pressed into shape by the stamping of native men. Both gánjá and charas are cultivated products and are chiefly used for smoking. *Bhúng* comprises the mature leaves, and in some parts of India the fruits and very young twigs also, but not the stems. By trituration with sugar and water a beverage is made which is known as haschish or bhúng. It is the least injurious form of cannabis and the one most frequently used. It is often prepared from wild plants growing around the native huts; consequently it is inexpensive and the greater part probably escapes duty. Various other preparations and natural products are known, but with these we are not concerned.

Historical.—The first European to investigate with any degree of scientific accuracy the action of Indian hemd was O'Shaughnessy[7] (1839). He used an alcoholic extract made by boiling freshly prepared gánjá with rectified spirit in a Papin's digester and evaporating the spirituous extract to dryness on a water bath. The substance thus obtained was very active; half a grain produced a distinct effect, and one and a half grains O'Shaughnessy regarded as a large dose. The estimated yield from fresh gánjá was 20 per cent. The process was subsequently modified by Robertson[8] (1846). He used a percolation apparatus, and extracted the drug with distilled alcohol. A green product was obtained, which he stated (probably erroneously) to be six times stronger than O'Shaughnessy's brown extract. The resin in a state of comparative purity was next obtained by T. and H. Smith[9] (1846). They digested bruised gánjá in successive quantities of warm water until the liquid came away colourless, then in sodium carbonate solution for two days at a moderate heat. The residue was next pressed, washed, and dried and then extracted with rectified spirit. The spirituous extract was now treated with milk of lime, filtered, and the excess of lime precipitated by sulphuric acid. A little animal charcoal was added, the mixture agitated, and filtered. Most of the spirit was now distilled off, water was added, and the remaining spirit allowed to evaporate gradually. The residual resin was then washed until free from acidity and bitterness and afterwards dried in thin layers. The yield was 6–7 per cent. Thus obtained the resin, to which they gave the name of *cannabin*, was extremely active; two-thirds of a grain produced narcosis and one grain decided intoxication. De Courtive[10] (1848), independently of Messrs. Smith, also isolated an active resin. This was obtained by extracting the leaves of Algerian hemp with spirit at a moderate heat, precipitating with water, re-dissolving the precipitated resin in alcohol, and evaporating. The yield was 9–10 per cent. Five centigrammes (about two-thirds of a grain) produced a distinct effect. Smaller quantities of a similar though less active product were obtained from plants grown in France.[11] Personne[12] (1857) controverted the results obtained by the brothers Smith. By distilling hemp with water he obtained an oily body[13] which he subsequently separated into two distinct compounds—*cannabene*, a liquid with the formula $C_{18}H_{22}$, and *hydride of cannabene*, a crystalline solid[14] with the formula C_6H_{14}; the latter body is physiologically inactive. Arutinianz believed[15] that he had obtained the hydride of cannabene, but as he concludes, according to Lapin, as to the identity of the two from the percentage of carbon present, this is doubtful. Personne attributed the effect of cannabis in great part to the cannabene he obtained, but on totally insufficient grounds, and he further states that by distilling Smith's resin with soda-lime at 300° C. (=572° F.) the residue was rendered inert. Considering the heroic treatment we may, perhaps, not question this, but as the dose given (from 0·2 to 0·5 *centi*gramme) would be inadequate to produce any effect proof is wanting[16] Messrs. Smith[17] themselves had shown that the activity of the resin was not due to any very volatile compound by exposing it to a temperature of 180° F. (82° C.) for eight hours freely to the air: the product was still as active as before. Vignola[18] (1895) has recently shown that Personne's cannabene is an impure sesqui-terpene. The pure substance he obtained by distilling in a current of steam, extracting the distillate with ether and subsequently purifying by repeated distillation from metallic sodium. It was then found to have the formula $C_{15}H_{24}$, and appears to be the same body as was obtained by Valenti[19] in 1880 from ordinary hemp. Moreover, Roux[20] proved by researches on animals that the ethereal oil was inactive, whereas an alcoholic extract was a decided intoxicant.

Nothwithstanding the investigations of O'Shaughnessy, Smith, and De Courtive it was thought that cannabis might contain some alkaloidal principle. Preobraschensky[21] (1876) obtained nicotine from a specimen of haschish obtained in Turkestan and from the flowering tops of the plants. As cannabis preparations are usually smoked in combination with tobacco, Dragendorff and Marquiss[22] suggested that the nicotine was derived from admixture with this substance—a supposition proved by Siebold and Bradbury[23] (1881) and Kennedy[24] (1886). Although Kennedy failed to obtain nicotine he was of opinion that an alkaloid was present, and Siebold and Bradbury also isolated a varnish-like base which they termed *cannabinine* and which gave alkaloidal reactions. The substance had an odour of coniine, but was not identical with it. Only two grains were obtained from ten pounds of drug. Arutinianz[25] and Masing,[26] on the contrary, obtained no alkaloid. In 1883[27] Hay discovered an alkaloid which produced tetanus in frogs and to which he gave the name of *tetano-cannabine*. It was present in very small amount and its elementary composition was not determined. His results led him to believe that other alkaloids were present, but these do not appear to have been isolated. Denzel[28] (1885) also obtained a tetanising alkaloid from hemp, but Warden and Waddell[29] (1884), working on large quantities of material, obtained no such compound. It is only fair to state that the process employed was slightly different to that of Hay, and a cat instead of a frog was used to determine its effect. A nicotine-like substance was obtained, but this proved to be physiologically inert

7 On the Preparations of the Indian Hemp or Gunjah; Calcutta, 1839. Also, Transactions of the Medical and Physical Society, Calcutta, 1839; Journal of the Asiatic Society, vol. viii.; Bengal Dispensatory, 1842, p. 579; Provincial Medical and Surgical Journal, 1843, pp. 343, 363, 397. The leaves of European hemp had previously (1821) been examined by Tscheepe (Chemische Untersuchung der Hanfblätter, Dissertation, Tübingen).

9 Ibid., vol. vi., p. 171 (see also p. 127).

10 Journal de Pharmacie et de Chimie [3], tome xiii., p. 427. Comptes Rendus, tome xxvi., p. 509.

11 Other investigations are also recorded about this time. Foy (Journal de Pharmacie et de Chimie [3], tome xiii., p. 350) extracted haschish with water, alcohol, acetic acid, white and red wines, butter, lard, and olive oil, but did not succeed in adding much to our knowledge. Martius (Gmelin's Handbook of Chemistry, Cavendish Society's edition, vol. xvii., p. 447) obtained a shining clear brown resin.

12 Journal de Pharmacie et de Chimie, tome xxxi., p. 46.

13 Bohlig (Pharmaceutisches Centralblatt, 1840, p. 519) had previously obtained an oily compound with similar physiological properties from European hemp.

14 Personne gives the formula in the old notation—$C_{36}H_{20}$ and $C_{18}H_{14}$. The formula of the last-named body is erroneously given in most books as $C_{18}H_{22}$. Personne gives the percentage composition C. 84·02; H. 15·98, which more closely approximates to C_7H_{16}.

15 Chemischen Untersuchungen des Indischen Hanfs. Dissertation, St. Petersburg, 1881. Quoted by Leib Lapin, p. 35.

16 Personne appears to have fallen into error with regard to the activity of Smith's resin. This is stated to produce a distinct action in doses of 0·05 centigramme. It should have been *gramme*. The dose of residue given, therefore, was too small to produce any effect, even with the original substance.

Jahns[30] (1887) also states that *tetanin* does not exist. More recently (1891) H. F. Smith[31] isolated an alkaloid resembling coniine from Indian hemp, but in such small quantity (0·75 milligramme per kilogramme) as to render it therapeutically unimportant. Still more recently (1895) Marino-Zuco and Vignola[32] prepared an alkaloid from various parts of "cannabis indica and cannabis sativa," but neither alkaloid possessed the characteristic action of cannabis compounds. Physiologically they were cardiac depressants, the alkaloid from cannabis indica being much the most powerful. The most recent investigators, Wood, Spivey, and Easterfield[33] (1896), failed to obtain any alkaloid from charas, and the bulk of evidence is therefore against the view that the effects of cannabis are due to an alkaloidal principle. In 1887 Jahns[34] obtained a crystalline base which he subsequently recognised as choline. He pointed out that chemically this body would explain the alkaloidal base obtained by previous observers, but it differs in crystalline form and solubility in ether from Hay's tetano-cannabine; physiologically, also, their action is different.

Of the more recent investigators Warden and Waddell[35] seem to have commenced upon the right lines. They argued that "as many of those addicted to the haschish form of intemperance obtain the intoxicating effects by smoking the plant in a pipe, it is to be expected that destructive distillation of the freshly prepared resin might yield up the active principle." They therefore made an alcoholic extract of the plant, added excess of caustic potash, and distilled. An amber-coloured oil came over, which, by exposure to the air or by the action of alkalies, rapidly assumed a dark brown colour. The oil contained ammonia, phenol, and other products of destructive distillation, and was "devoid of narcotic and irritant properties." One drachm administered to a cat produced no sensible effect. Leib Lapin[36] (1894) isolated a substance which he termed *cannabindon*, and which appears to possess the physiological action of fresh cannabis preparations. This he obtained by warming the plant with milk of lime and extracting with ether. The ethereal extract he treated successively with acetic ether, alcohol, petroleum ether (twice), and water, the precipitate being rejected each time. The second and third fraction obtained by precipitating with water contained impure cannabindon; this he subsequently purified. Last year, Cowan Lees[37] expressed a belief that watery extracts contained some active ingredient of cannabis. He describes good effects from the use of such preparations, but I am not aware that any scientific explanation has yet been given of them.

The most important results of recent years are those of Wood, Spivey, and Easterfield.[38] Working with charas they isolated from an ethereal[39] extract—(1) a terpene, boiling-point from 160° to 180° C., yield 1·5 per cent.; (2) a sesqui-terpene, boiling-point from 258° to 259° C., yield 2 per cent.; (3) a paraffin ($C_{29}H_{60}$?), melting-point from 63° to 64° C., yield 0·15 per cent.; and (4) a toxic red oil or resin ($C_{18}H_{24}O_2$), boiling at 265° C. under a pressure of 20 m.m. Hg., yield 33 per cent. As we should expect from its method of preparation the resin is extremely stable. It yields mono-acetyl and mono-benzoyl derivatives and is unacted upon by alcoholic potash, and, below 150° C. by hydriodic acid and phosphorus. It is insoluble in water, but soluble in alcohol, ether, benzene, and organic solvents generally. It appears to be the active constituent of the drug, and the authors have succeeded in isolating it from several cannabis preparations in the market—viz., from Smith's cannabine, 80 per cent.; Merck's cannabinon, 50 per cent.; Merck's ethereal extract, 26 per cent.; and Merck's cannabis resin, 20 per cent. As the compound contains at least one hydroxyl group the authors recommend the name *cannabinol* for it. Further investigations are being made upon its constitution, but as yet no further communication has been made.

As previously mentioned, all samples of charas are not of the same quality. From a second sample of this substance, undoubtedly inferior to the first, Easterfield and Wood were only able to extract 15 per cent. cannabinol.[40] Another sample of charas sent to me by my friend, Surgeon-Lieutenant John Stephenson, I.M.S., and obtained in the cantonments at Peshawar, was of intermediate quality. Various other preparations of cannabis indica (Merck's. Bombelon's, Denzel's, Gastinelli's, &c.) are known, and even largely used, but as these have not added much to our knowledge of the chemistry of this body I shall not mention them further. By oxidising cannabis resin with nitric acid Bolas and Francis[41] (1868) obtained a crystalline substance oxy-cannabine ($C_{20}H_{20}N_2O_7$), but the physiological action of this compound was not determined. Flückiger[42] failed to obtain it.

Personal experiments.—The substances isolated by Wood, Spivey, and Easterfield were passed on to me for pharmacological investigation. Owing to the pressure of other work this investigation is not yet finished but as soon as time permits it is hoped to complete it and give a full account of the pharmacology of this drug. The present experiments are of a purely personal character and are merely to establish the activity of cannabinol and introduce it into therapeutics. The experiments themselves I intend to comment upon at some future time.

I was under the impression that I had taken a small dose of impure cannabinol some time previously without any effect, when, on the afternoon of Feb. 19th last, whilst engaged in putting up an apparatus for the distillation of zinc ethyl, I took from 0·1 to 0·15 gramme (from 1½ to 2 grains) of the pure substance from the end of a glass rod. It was about 2.30 P.M. The substance very gradually dissolved in my mouth; it possessed a peculiar pungent, aromatic, and slightly bitter taste, and seemed after some time to produce slight anæsthesia of the mucous membranes covering the tongue and fauces. I forgot all about it and went on with my work. Soon after the zinc ethyl had commenced to distil — about 3.15 — I suddenly felt a peculiar dryness in the mouth apparently due to an increased viscidity of the saliva. This was quickly followed by paræsthesia and weakness in the legs, and this, in turn, by diminution in mental power and a tendency to wander aimlessly about the room. I now became unable to fix my attention on anything and I had the most irresistible desire to laugh. Everything seemed so ridiculously funny; even circumstances of a serious nature were productive of mirth. When told that a connexion was broken and that air[43] was getting into the apparatus and an explosion feared I sat upon the stool and laughed incessantly for several minutes. Even now I remember how my cheeks ached. Shortly afterwards I managed to collect myself sufficiently to aid in the experiment, but I soon lapsed again into my former state. This alternating sobriety and risibility occurred again and again, but the lucid intervals gradually grew shorter and I soon fell under the full influence of the drug. I was now in a condition of acute intoxication, my speech was slurring, and my gait ataxic. I was free from all sense of care and worry and consequently felt extremely happy. When reclining in a chair I was happy beyond description, and afterwards I was told that I constantly exclaimed, "This is lovely!" But I do not remember having any hallucinations: the happiness seemed rather to result from an absence of all external irritation. Fits of laughter still occurred; the muscles of my face being sometimes drawn to an almost painful degree. The most peculiar effect was a complete loss of time relation: time seemed to have no existence: I appeared to be living in a present without a future or a past. I was constantly taking out my watch thinking hours must have passed and only a few minutes had elapsed. This, I believe, was due to a complete loss of memory for recent events. Thus, if I walked out of the room I should return immediately, having completely forgotten that I had been there before. If I closed my eyes I

forgot my surroundings and on one occasion I asked a friend standing near how he was several times within a minute. Between times I had merely closed my eyes and forgotten his existence. Another peculiar effect was the occurrence of lucid intervals. They seemed to come on suddenly, sometimes but not always as if the result of an effort of the will. They lasted a variable time, being shorter when the symptoms of intoxication were most marked. In them I could converse in a fairly rational manner and even direct the work of the laboratory to a certain extent. But even in my sanest moments I was deficient in will power. I offered no resistance to being pulled out of the chair and made to walk the laboratory floor, and when asked if a medical man might be sent for I objected, but had no power to say "No." At one time, although walking rapidly, I felt cold and had to adjourn to an adjoining room where a fire was burning. I stood before it and thought how strange things were. I had a hazy notion of having been rational once and I wondered if ever I should be rational again. I was devoid of feeling, fearless of death, and even insensible to the feeling of others: if the friend by my side had died I think I should have laughed. About 5 o'clock a medical man was sent for. I had now been rational for nearly half an hour, but as soon as he appeared I again fell into an acute delirium and performed the same antics I had performed before. I knew I was acting foolishly, but I could not help it. Gradually I became calmer and then I told him what I had done. I could not have been devoid of reasoning power, for when he suggested an emetic I argued that it would do little good, as most of the substance must have been absorbed; I was too happy to be disturbed in that way. I told him I was getting better, but soon afterwards I again lost control. At 6 o'clock I had two cups of coffee and then feeling somewhat better walked home. The street seemed longer than usual and its lamps almost interminable, but although I had looked across the quadrangle previously this was the only illusion of distance that I noticed. The fresh air and exertion revived me. I ate a good dinner, afterwards read a little, and retired to bed at 11 o'clock without having experienced any symptoms of sleepiness. I quickly fell asleep and woke at 7 A.M. My memory had not quite returned to normal, but otherwise I was quite well. At 11.30 slight tenesmus and relaxation of the bowels occurred.

Although these notes were written immediately after the experiment many things which happened are not recorded; of many of them I have not the slightest recollection. I am told that early in the intoxication I drank water frequently, even out of my hand, but I have no remembrance of it. During the action of the cannabinol my pulse rose from 60 to 90 per minute, sensibility as determined by pinching was blunted, and my appearance was described as "ashy pale." The pupils were dilated somewhat,[1] but throughout reacted to light and accommodation. At no time do I remember having had hallucinations; no unpleasant after-effects were experienced, and the drug appears to possess no constipating action.

About three weeks after the last experiment 0·05 gramme (¾ grain) of cannabinol was taken (2.35 P.M.). No effect was felt for four hours; then symptoms similar to those I have described, but less severe, occurred. First, there was dryness, or rather sliminess, of the mouth and a peculiar taste. This was soon followed by weakness in the legs and intoxication. After dinner (7 P.M.) I sat in an easy chair and closed my eyes. A dreamy state supervened and visions of a grotesque character appeared. A regiment of soldiers was seen marching; their movements gradually increased to running, their legs went faster and faster, until finally the whole regiment was lost in a number of rapidly revolving circles. Then visions of ugly boys were seen; from slight ugliness greater ugliness developed, and this increased so as to become ridiculous. Similar hallucinations occurred in a friend. Accompanying—probably preceding—this dreamy state was a pleasurable tingling all over the body, sometimes and in some places (the cheeks especially) becoming almost painful. Time seemed long, but it did not pass with the same rapidity as on the former occasion, or rather I did not experience the same forgetfulness; external relations were more connected. Gradually I grew sleepier, and it was with difficulty that I kept my eyes open. I did not succeed in sleeping in a chair, and at 9 retired to bed. Sleep did not follow for some time and I awoke at 6 A.M. As before, slight relaxation of the bowels occurred. Much smaller doses (0·01 gramme, about ⅙ grain) produced no sensible effect.

A few months afterwards a non-medical friend complained of sleeplessness and at my request took 0·05 gramme (¾ grain) cannabinol made into a pill with starch. He afterwards supplied me with the following account: "The pill was taken at 10.30, just before retiring for the night. I probably dozed a little at first, but I remember hearing the clock chime 11.30 and later 11.45. Almost immediately afterwards I began to see strange sights, which passed so rapidly that I had no time to examine them in detail. One that I remember was a bow-legged boy running with a chest of tea between his legs; another seemed like a procession of females in the distance, but on closer examination turned out to be coffins; these quickly melted away, leaving nothing but confusion. The clock struck 12, then 12.15. I remember nothing further until I awoke refreshed at 8 A.M. from a sound slumber." Cannabinol has been used in a few other cases as a hypnotic and with success, but at present I do not wish to enter into its uses as a medicine or even to recommend it as a therapeutic remedy. Considerable experience is always needed to establish the usefulness of any medicine, and this I have not yet been able to obtain. All that is claimed for this substance is that it is active—as active as any preparation yet made—and pure. Whether it will change by keeping or not time alone can tell. Perhaps when greater leisure enables me to complete the pharmacology of the drug I may be able to speak more definitely upon this point.

Of the other constituents of charas the terpenes are the most important. These have no peculiar action; they act as terpenes and in doses of 0·5 gramme (from 7 to 8 minims) are apparently without effect. It is possible that the good effects obtained by some physicians (Silver, McConnell, Bond, Edwards, &c.) in cases of menorrhagia, dysentery, &c., may be partly due to these constituents, but of this I hope to speak later. In conclusion, I express my thanks to Mr. Wood, Mr. Spivey, and Mr. Easterfield for the material with which they supplied me; to my friend, Mr. Stephenson, for samples of cannabis; and to Mr. Heath for notes of his observations during the time I was under the influence of the drug.

Cambridge.

[1] In the case of the Brothers Smith they were contracted (Pharmaceutical Journal, vol. vi., p. 173).

ON CERTAIN APPARENTLY ORGANIC TUMOURS OF THE ORBIT WHICH DISAPPEAR UNDER MEDICINAL TREATMENT.[1]

BY SIMEON SNELL, F.R.C.S. EDIN.,
OPHTHALMIC SURGEON TO THE SHEFFIELD GENERAL INFIRMARY.

I HAVE for a long time been familiar with the clinical fact that internal medication can in certain instances bring about the disappearance of orbital tumours. This is true, moreover, of tumours which exhibit features rendering differentiation from those of a malignant or certainly organic nature difficult, and but for the effects of treatment the distinction would perhaps be impossible without an examination of their minute structure. Just now I am thinking particularly of orbital growths occurring at about the middle period of life, when those of a malignant nature would be prone to arise. I propose to relate recent instances illustrative of this contention.

Panas of Paris, at the annual meeting in London of the British Medical Association in 1895,[2] brought forward a very valuable and instructive paper dealing with pseudo-malignant tumours of the orbit. He expressed the opinion that because dispersion of these growths followed the administration of iodide of potassium it was a mistake to regard syphilis as the only cause, and he believed that a "number of neoplasms thought to be lymphomas, sarcomas, or syphilomas ought to be attributed to the dyscrasia produced by some toxin." He spoke of a class of infectious tumours, the syphilitic being an example but not the only one. We are of course all familiar with the frequent impossibility of getting a specific history even in

[1] Read before the Sheffield Medico-Chirurgical Society, Oct. 22nd, 1896.

[2] Brit. Med. Jour., vol. ii. 1895, p. 955.

Hosted by Google

cases which admit of little doubt of syphilitic taint. My experience in a fairly large number of instances of syphilis acquired in an innocent, non-venereal manner has impressed me with the fact that it is much more possible for an individual to become syphilised without being aware of the nature of the affection than might be supposed. But Panas' observations are, nevertheless, of interest as he recounts instances which have undergone apparent cure with treatment by arsenic and other remedies which can hardly be regarded as anti-syphilitic.

CASE 1.—A short time since I recorded[3] the case of a middle-aged man who was admitted under my care into the Sheffield General Infirmary with what was regarded as inflammatory enlargement of the right lacrymal gland of several weeks' duration. It formed a very noticeable tumour at the outer and upper part of the orbit, rendering the eye somewhat prominent and materially interfering with the movements of the eyelid, which was also somewhat œdematous. The tumour continued to enlarge in spite of the administration of iodide of potassium—in fact, the commencement of the use of this drug was characterised by a somewhat rapid increase in size of the enlarged gland. Later, however, it became more stationary, and after the patient had been in the infirmary for some weeks my surgical colleagues, whose opinion I sought, were disposed to regard the growth as a sarcoma and suggested early removal. Before taking this course, however, as the man was anxious to return to his home he was allowed to do so on his promising to report himself after a short interval. This he did in a few weeks' time. The tumour had then become considerably lessened in size. No treatment had been adopted since his leaving the infirmary. A fortnight later he was again admitted. The edge of the tumour was all that could then be felt. In the course of the next few weeks the whole of the growth had disappeared and the eye had resumed its normal characteristics. There was no history of mumps or any general disorder with which to associate the enlargement of the gland. The only explanation offered was one by the man himself, who attributed the disorder to the fact that as an agriculturist he had been using sheep dip made particularly strong with sublimate, but there was no evidence of any wounds or abrasions on the hands, nor had there been salivation or implication of salivary glands or other symptoms suggestive of poisoning.

The case just related, much as it appeared at one time like a malignant tumour was in all probability only an instance of chronic inflammatory enlargement of the lacrymal gland. The cases to be now mentioned are more pertinent to the object of this paper.

CASE 2.—A woman, aged forty years, was sent to me on Nov. 20th, 1895, by Mr. Tristan of Retford owing to a prominence of the left eyeball due, he feared, to a tumour of the orbit. The prominence of the globe was first noticed about three months before and had recently become rapidly worse. For a considerable period prior to this she had suffered a great deal from headache confined to the left side. Treatment had, however, rendered this much less. On examination I found that the left eyeball was distinctly pressed forward, but that there was no marked interference with the movements of the globe. The upper eyelid was somewhat reddened and a trifle œdematous. A tumour was readily found at the outer part of the orbit; it was detected by the finger running also into the orbit above the globe, but the part where it was chiefly situated was on the floor of the cavity extending to the inner side. Here it was distinctly felt projecting as a rounded, somewhat hard, growth over the edge of the orbit. It was also slightly tender to the touch. The tumour was thus an extensive one, but the ophthalmoscope gave no evidence of interference with the intra-ocular circulation. Vision was unimpaired and there were no indications of parts adjacent to the orbit being affected. The patient had been married for twenty-three years. A son, aged twenty-one years, was living. Inquiry afforded neither myself nor Mr. Tristan any other suspicion of specific history than that many years ago she had had miscarriages, the last being ten years previously. The opinion expressed to her medical attendant was that she had an extensive tumour in the orbit, that it would probably require removal, and to get rid of it entirely it would be necessary to remove also the globe. But notwithstanding the absence of a specific history (which I may say he confirmed) I mentioned that I had seen so many growths disappear under iodide of potassium that I should be disposed to give her a course of that drug before resorting to surgical measures. Mr. Tristan adopted this suggestion. On Dec. 15th he wrote that "the tumour has subsided in a marvellous manner," and this dispersion had continued when she paid me a visit on the 24th. At this date I found that the proptosis had nearly gone and that there was apparently little difference between the two eyes, but along the lower border of the orbit the edge of the tumour could be just felt much reduced in size but still a trifle tender to the touch. Starting with a dose of five grains of the iodide she had for some time been taking sixty grains daily. On Feb. 11th, 1896, she paid me another visit. At this time there was nothing to notice in the appearance of the eye as different from the other. The finger passed along the lower and inner wall of the orbit could no longer detect any tumour.

About the same time that the previous patient first came under observation, another woman, somewhat older, appeared among my patients at the infirmary. She had a tumour in the right orbit, displacing the eyeball forwards, but it was not more extensive than that in Case 2. It involved the inner and lower part of the orbit. The onset had been more gradual and it was of longer duration than in Case 2 and was associated with some pain. It would be about as correct to assume a specific taint in one as in the other, and yet in this patient the iodide, tried for a time, exerted no influence, and it was deemed necessary to remove the growth, a proceeding to do which effectually involved the sacrifice of the globe. The tumour proved to be a sarcoma growing from the inner and lower part of the orbital wall.

CASE 3.—In October, 1894, I had under treatment at the infirmary a man, aged forty-two years, who for several weeks before coming to me had noticed that the left upper lid was slightly swollen, and latterly he had suffered somewhat from aching pain. He had a good family and personal history and denied any venereal taint. In addition to the somewhat swollen condition of the eyelid already mentioned the left eyeball was more prominent than its fellow. The finger carried between the globe and the upper wall of the orbit taught that the space was filled up by some large growth which was firm feeling and somewhat nodular. The movement of the globe upwards was also interfered with and the eyelid drooped, and he was able to raise it very imperfectly. During the short time he attended among my out-patients his condition became rather aggravated. At this period he was shown at the Sheffield Medical Society. The presence of a tumour was recognised and its possibly malignant character was discussed by several members who saw the patient. He was admitted into the infirmary and at once placed upon iodide of potassium. A steady improvement commenced which continued until the tumour had become completely absorbed, the appearance of the two eyes being similar and evidence of the former trouble being altogether removed.

The cases mentioned bear a very close clinical resemblance to tumours regarded as sarcomatous and in which the diagnosis has been confirmed by the microscope after the growth has been removed. There was the same evidence to the touch of a somewhat hard, elastic tumour, not fluctuating or pulsating, and somewhat nodular on the surface as an organic tumour would present. Treatment proved that they could be dispersed without operation, and therefore it appears to me that the lesson to learn is one that Panas enforced in the paper to which I have already directed attention—viz., that before resorting to surgical measures for orbital tumours the effects of internal treatment should be tried. It is not necessary that iodide of potassium with or without mercurial inunction should be employed, for Panas mentions the benefit derived from arsenic and other remedies. Panas also suggests that serum, according to the nature of the infection which has been at work, should be used.

The simplest way of accounting for the presence of such tumours as I have referred to is, of course, to presume that they are syphilomas and very naturally to discount the absence of specific histories. If we are to believe that, as a consequence of dispersion following the administration of the iodide, the nature of the tumour has been proved nothing more, of course, can be said. I confess, however, that my feeling is that such tumours as have been referred to in this short communication are not necessarily syphilitic, and the observations of Panas as to unilateral and bilateral orbital growths afford strong support to such a contention.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A NOTE ON DECOMPOSITION OF CHLOROFORM, AND SICKNESS.

BY DAVID NEWMAN, M.D.,
SURGEON TO THE GLASGOW ROYAL INFIRMARY;
AND
WILLIAM RAMSAY, PH. D., F.R.S.

EARLY in the history of chloroform it was noticed that the agent had a tendency to undergo spontaneous decomposition on exposure to air and light, and although within recent years great care has been taken by manufacturers of the drug to produce as pure an article as possible, nevertheless, the fact remains that chloroform is not stable and rapidly deteriorates as an anæsthetic. When freshly distilled chloroform is administered, the vapour is easily inhaled, having a sweetish and not unpleasant taste and odour. It produces little or no irritation in the air passages, little excitement of the patient is observed, and if the agent is carefully given sickness, fainting, and irregularity of the pulse and respiration seldom occur during its administration. But if chloroform is kept in a bottle containing air, exposed even to feeble light, changes are produced in the drug which render it less suitable as an anæsthetic. The change is due to the formation of carbonyl chloride and hydrogen chloride, according to the equation $CHCl_3 + O = HCl + COCl_2$. These substances render the vapour slightly pungent in odour, and on inhalation it produces irritation in the air passages. The period of excitement of the patient is more marked and the liability to sickness during and after anæsthesia is greater.

During the last six months the effects of freshly distilled chloroform and of chloroform supplied in the ordinary way have been contrasted, greatly to the advantage of the former. It has been found, however, that distillation is not necessary, as by shaking the chloroform with slaked lime and filtering the irritating products of decomposition are eliminated, as, indeed, theory would predict; for the hydrochloric acid is, of course, at once acted on by the lime, giving calcium chloride and water, and the carbonyl chloride, to the presence of which the sickness is probably to be ascribed, is resolved into carbonate and chloride of calcium, thus—$COCl_2 + Ca(OH)_2 = CaCO_3 + CaCl_2$. In illustration the three following cases may be mentioned:—

CASE 1.—A man was operated on three occasions. For the two first the chloroform given had been in the wards for not more than ten days, and was kept in a well-stoppered bottle away from direct light; but the bottle contained some air. Each operation lasted fully an hour, and on both occasions the pulse became very irregular and feeble so as to necessitate artificial respiration. While recovering from the effect of the chloroform he was very sick, and the sickness continued for two days after the first operation, and for three days after the second. The third operation lasted for one and a half hours. Chloroform which had been kept with slaked lime in it and filtered before use was employed. The patient, although much feebler through disease, remained well during the operation, and there was no sickness for twelve hours, when he suddenly became sick, but this passed off in a short time.

CASE 2.—A woman had been under chloroform four times and she was invariably very sick while coming out and afterwards, the sickness lasting for twenty-four hours or more. When chloroform treated with lime was used, on coming out of the anæsthetic sickness occurred for a few minutes only.

CASE 3.—A man was under chloroform four times. On the first and third chloroform as supplied by the druggist was used, and it was not more than twelve days old. After both operations there was severe sickness, lasting for thirty-six hours. On the second and fourth administrations freshly distilled chloroform was employed with no sickness resulting.

As a matter of experience it was found that freshly prepared chloroform is more reliable as an anæsthetic, and is less likely to produce sickness during or after administration, and the risks of anæsthesia are probably increased by the decomposition of chloroform when kept for any considerable time exposed to air and light. Even with fresh, chloroform sickness may occur if the patient is allowed to come out during the operation, but the quantity of acrid mucus is very small in amount as compared with what is seen when older chloroform is given. Perfectly pure chloroform is said to be a much less stable body than chloroform containing alcohol. As an instance of the instability of pure chloroform it may be mentioned that a sample left in a half-full stoppered bottle from July till October, 1896, smelt as pungent as hydrochloric acid, gave with baryta water a copious precipitate of carbonate, and was absolutely irrespirable.

Glasgow.

UNUSUAL CASE OF CARCINOMA OF THE BREAST.

BY W. S. CRAWFORD, B.A. CANTAB., F.R.C.S. EDIN.,
SENIOR ASSISTANT SURGEON, LIVERPOOL CANCER AND SKIN HOSPITAL.

IN the beginning of September, 1892, a fresh-complexioned, thin woman, aged thirty-one years, came under my care at the Liverpool Cancer and Skin Hospital. She was unmarried. Some months before admission the patient had received a blow on the right breast which caused her a good deal of pain for some time. She did not notice any swelling. Three months after receiving the blow she found a lump in her right breast about the size of a marble, situated above and to the outer side of the nipple; it was freely moveable and quite free from pain. On the patient's admission to hospital, some four months later, the lump had attained the size of a tennis ball. It was very hard and adherent to the skin. The nipple was retracted. The axillary glands were hard and enlarged. It was a well-marked scirrhus of the breast. The breast was removed and the axilla cleared. The sections were found to be hard, spheroidal-celled carcinoma. On Nov. 25th, 1896 (four years later), the patient again presented herself at the hospital. Her general appearance was but little changed. She gave a history of having wrenched her right arm and hurt her right breast eight months before. There was no lump of any kind then. The present local condition is as follows. There is a large oval-shaped tumour distending the skin, which is ulcerated in a circular patch two inches in diameter over the most prominent part of the growth. The ulcerated area is concave; it bleeds readily on the slightest interference. Towards the axilla a flattened portion of growth is felt extending from the main mass and firmly adherent to the pectoral muscles, but not certainly to the bony wall of the chest. About two inches lower down than the main mass there is a small area somewhat discoloured about the size of a penny, intensely hard, and two or three small nodules in the immediate neighbourhood, evidently recurrences in the superficial lymphatics. The right armpit is clear, but the left contains a mass of enlarged and undoubtedly cancerous glands. The main recurrence commenced, according to the patient's description, immediately above the old cicatrix. It now involves the scar and the tissues on each side.

Remarks.—Her father's sister died from carcinoma of the breast which followed an injury. The patient's primary growth, as well as recurrence, followed definite injuries. In so young a patient it was pleasing to find so long an immunity period—three and a half years.

Liverpool.

NOTE ON A CASE OF RUPTURE OF THE HEART.

BY CECIL ROBERTSON, M.B., C.M. ABERD.

CASES of rupture of the heart from external violence without penetration of the chest are by no means of frequent occurrence. Erichsen, in the last edition of his "Science and Art of Surgery," says that Gamgee was only able to collect twenty-two published cases. In the majority of these cases the blow was directly over the cardiac region. For two reasons I think the following case is not unworthy of being recorded—(1) the small number of recorded cases; and (2) that the heart in this case was ruptured by indirect violence.

Hosted by Google

An apparently healthy man aged forty-nine years opened the door of a railway carriage just as the train commenced to move and fell somewhat heavily on his left shoulder. On being asked by the officials if he had hurt himself he replied "No" and proceeded some two or three hundred yards from the station to his work, where he died within three-quarters of an hour of his falling from the train. On post-mortem examination I found the pericardium intact but distended with a mass of blood-clot and fluid blood. In front of the left auricle was a laceration one and a quarter inches long through which a piece of clot protruded. The wall at the seat of the laceration was considerably thinned; both ventricles were very much hypertrophied, the whole organ weighing 22 ozs. Beyond a slight abrasion over the right knee there was no external evidence of any injury, and there is little doubt that the cause of the rupture was the violent impact of the left shoulder on the platform.

RADCLIFFE INFIRMARY, OXFORD.

A CASE OF SUPPOSED PASSAGE OF THE STOMACH THROUGH A RENT IN THE DIAPHRAGM INTO THE PLEURAL CAVITY, THE RESULT OF AN INJURY; RECOVERY.

(Under the care of Mr. A. WINKFIELD.)

ESCAPE of the contents of the abdomen into the pleural cavity in consequence of injury of the diaphragm is a very rare condition, the symptoms produced by such escape being well exemplified by the careful report of this case. Such hernia (as it is, perhaps, wrongly called) is usually without any proper sac, although it may push some partially-ruptured pleura in front of it, and is nearly always on the left side. The injury to the diaphragm may be caused by a stab which has penetrated the chest wall, as in cases recorded by von Horock[1] and Pestempski,[2] the latter of whom successfully sutured the opening in the diaphragm after returning the protrusion, the wound of the chest wall having been enlarged; or more commonly a rupture of the muscular tissue is caused by a buffer accident, and the protrusion into the chest follows immediately. That such injury is not by any means immediately fatal, though producing profound disturbance at the time and troublesome symptoms later, is shown by the cases of Jacobsen[3] and Farwell.[4] Both patients ultimately died from intestinal obstruction the direct result of strangulation, but this did not take place until eighteen and sixteen years afterwards. Both Nauman[5] and O'Dwyer[6] have operated unsuccessfully for diaphragmatic hernia; the former was unable to replace the escaped contents of the abdomen after operation from the abdomen in consequence of adhesions; the latter, who opened the chest expecting to find an empyema, resected parts of the ninth and tenth ribs, reduced the hernia, and sutured the opening, but the boy, aged three and a half years, died six hours later.

A boy, aged five years, was admitted into the Radcliffe Infirmary under the care of Mr. Winkfield with the history that he had fallen with a heavy iron gate upon him. He was collapsed and cyanotic, and some brandy-and-water was administered by the mouth. The left side of the chest was almost motionless and was tympanitic in resonance; it was at first supposed to be pneumothorax, but an exploring needle passed in the fifth left interspace posteriorly drew off brandy-and-water instead of air, as was expected. There were some bruising and tenderness on the lower part of the right side of the thorax; the breathing on that side was loud and exaggerated; the left side moved but little in respiration. At the apex there were dulness and tubular breathing; below the left apex there were tympanitic resonance and distant metallic tinkling. Posteriorly there was some slight dulness with distant breath sounds. The heart dulness was obliterated; its sounds were most distinct above the sixth interspace on the right of the sternum, where its beat could be felt. Upon giving him liquids to swallow distant metallic sounds could be heard in the left half of the chest. For some three days after admission he was in a state of collapse, he could not sit up, there was marked dyspnœa, and upon any slight exertion he became cyanotic. After a few days he began to improve generally, but the condition of the chest remained the same; he complained of severe pain in his left leg and at the back of the knee, but no injury could be felt in that region, and the hip upon examination was evidently free from injury or disease. He had lost flesh a good deal, but was now (Oct. 6th) able to get about without much dyspnœa, and he took food without pain; the physical signs of the condition of the chest remained much as before. There has been no material rise of temperature throughout the case.

Remarks by Mr. WINKFIELD.—The patient was lately shown before the Oxford Medical Society, when several gentlemen present examined him and agreed that the above diagnosis was probably the correct one. I mentioned two cases which I had previously met with. One was that of a blacksmith who over-reached himself when striking a blow with a heavy hammer, and was brought to the infirmary suffering from severe pain in the upper part of the abdomen. After lying quietly in bed for a few days he was suddenly seized with vomiting and became collapsed and died. Upon post-mortem examination there was found a rent in the left side of the diaphragm; the stomach, spleen, and portion of the large intestine had passed through the rent into the pleural cavity. The second case was that of a boy who had been squeezed between the buffers of railway waggons. He was admitted soon after the last case. His aspect and condition were so like those of the last patient that attention was called to them. Upon examination a very similar condition to that of the boy whose case is related above was found. The patient remained in the infirmary for some weeks and then, leaving the hospital, he was lost sight of.

NORFOLK AND NORWICH HOSPITAL.

A CASE OF DEATH FROM HÆMORRHAGE FOLLOWING OPERATION FOR TONGUE-TIE; NECROPSY.

(Under the care of Mr. S. H. BURTON.)

FOR the notes of the case we are indebted to Mr. Hamilton A. Ballance, house surgeon.

A male child was born after a natural delivery at 5 P.M. on Dec. 21st, 1896. The mother was attended by a midwife temporarily employed by the Lying-in Charity of Norwich, though she had not obtained its certificate. About an hour after the birth the midwife said that the child was tongue-tied, and using a sharp-pointed pair of scissors she proceeded to liberate it. She did not notice bleeding at the time of the operation, but on the evening of the same day blood was observed by the friends to be issuing from the child's mouth. At noon the next day (the 22nd) as the bleeding continued the father went to the midwife's house and fetched her to the case. The woman told the parents that the child was all right and that there was no need to be frightened. On this day the child passed dark blood by the bowel. The hæmorrhage did not cease and the midwife was, therefore, again fetched on the evening of the following day. She then washed the mouth and the face of the child with warm water. The father requested that a medical man should be called in, but the midwife said that it was unnecessary and that if she was to blame she would take the responsibility. Eventually, however, she took the child herself to a medical man, who, after examining him and giving directions to the friends as to treatment, recommended that he should be taken to Mr. Burton. Mr. Burton found arterial bleeding going on in the anterior part

Hosted by Google

of the floor of the mouth and placed two ligatures on the bleeding points. He then sent the child to the Norfolk and Norwich Hospital, where he was admitted at 10 P.M. on the 23rd. On admission the child was pale and weak and the pulse was rapid and feeble. He was small, weighing only five pounds. On examination there was seen to be a cut in the floor of the mouth under the tip of the tongue between one-half and three-quarters of an inch long, and extending from just to the right of the middle line away to the left, along the junction of the tongue and the floor of the mouth and exposing the muscular substance of the tongue. The bleeding seemed to have stopped from the time of the application of the ligatures. The child was put to bed, but died rather suddenly in the early hours of the next morning (the 24th). While in the hospital he passed some dark blood by the bowel, having apparently swallowed the blood as it exuded from the wound in the mouth.

Necropsy.—Post mortem all the organs were found to be healthy, though extremely anæmic. In the stomach and intestines throughout almost the whole of their length there was much dark semi-fluid blood. A ligature was seen on the left ranine vein, but whether this vessel or the artery was the source of the major portion of the blood lost was not made out.

Remarks by Mr. BALLANCE.—The above case may be of interest to medical men owing to the prominence of the midwives question at the present time. An inquest was held and the jury returned a verdict of "Death from misadventure." They also recommended that in future a medical man should be consulted should this operation be thought necessary, and considered that the midwife was deserving of censure for undertaking it. At the inquiry the woman stated that she had frequently performed the operation before, always using sharp-pointed scissors, and that this was the first accident she had encountered.

BRADFORD GENERAL INFIRMARY.

A CASE OF PANCREATIC CYST ASSOCIATED WITH GLYCOSURIA AND GALL-STONES; NECROPSY.

(Under the care of Mr. HORROCKS.)

THE change which has taken place in our estimation of the surgical importance of the pancreas is well shown by a reference to earlier editions of surgical text-books. In France, for instance, in his work on surgery (1877) Tillaux states: "Of all the viscera contained in the abdominal cavity that of least interest to the surgeon is the pancreas, owing to its deep situation." The whole subject was dismissed in a few lines. In a new edition (1888) its importance was considered to justify a whole chapter. In this country one of our text-books[1] (1888) devotes a paragraph to the subject of cysts of the pancreas, and speaks somewhat uncertainly especially as regards treatment. In the last edition (1895) this subject is considered at some length and the treatment clearly laid down. The teaching is less certain as regards the causation of the cysts: "When they are traumatic in origin it seems probable that laceration of the gland with hæmorrhage occurs and that this is followed by escape of the secretion from the torn ducts. In the cases in which there is no evidence of injury it has been suggested that a retention cyst forms as the results of some obstruction of the duct." The account of the post-mortem examination in this case makes it possible that the gall-stone which was found in the common duct was an important factor in the causation of the cyst of the pancreas, and the observation is therefore one of considerable interest. For the notes of this case we are indebted to Dr. Bruce Buchanan Morton, resident dispensary surgeon.

The patient, a man aged fifty-six years, was admitted to the Bradford General Infirmary on Nov. 19th, 1896, suffering from pain of varying intensity in the region of the stomach, with nausea, occasional vomiting, a constant sense of "heaviness" and languor of three months' duration, and a tumour first noticed two months previously in the upper part of the abdomen. Since his illness began he had been a little jaundiced and related the passage of several small greenish stones. He also said that he had lost flesh steadily but had had no injury and could assign no cause to account for his condition. On examination the patient was found to be wasted; his skin was sallow and dry, the conjunctivæ were slightly yellow, and his breath emitted a sweetish odour. The thoracic and abdominal examinations disclosed, as irregularities, a distant sound of the heart at the site of maximum impulse, an encroachment of the stomach note on to the left pulmonary areas, and the presence of a tumour mostly occupying the left epigastric and hypochrondriac regions. It was of the size of a fœtal head presumably, firm, unmoved by respiration, but vibrating with aortic pulsations. Percussion over the tumour gave a dull note continuous with the left hepatic dulness, but it was elsewhere surrounded by a tympanitic note. The urine was pigmented, of specific gravity 1025, and contained casts, epithelial and hyaline; also albumin and sugar—a quantity of the latter. The patient looked ill. His pulse was 140. On the 20th three ounces of greenish-brown turbid fluid were removed from the tumour by aspiration. The fluid was alkaline, albuminous, contained no bile, pigments or sugar, and emulsified oil. Its specific gravity was 1009. All treatment proved unavailing and the patient sank and died at 4 A.M. on Nov. 21st.

Necropsy.—Post mortem a large cyst with walls of tough fibrous consistence (one-fifth of an inch thick) and a potential capacity of about two pints was discovered in the lesser peritoneal cavity, with adhesions to the stomach and to the concavity of the spleen, and occupying the site of the normal pancreas. It had a smooth, pale inner surface with shallow sacculations, some of which and the floor of the cyst were occupied by a green, tough, loose substance of a colour like that of boiled spinach. On the exterior of the cyst no normal pancreas could be found and the duct of Wirsung could not be entered by a probe. At the duodenal end of the cyst, however, a stone the size of a pigeon's egg was felt to be loosely impacted in the contiguous common bile-duct and could only be removed by an incision into the gall-bladder, which was filled with a loosely-packed mass of gall-stones, some of which occupied the common duct. The intestines contained no gall-stones, the kidneys to the naked eye appeared normal, and other organs as well. The microscopical examination of a section of the cyst wall by Dr. H. B. Gladstone showed clearly glandular remains here and there in dense fibrous tissue.

Remarks by Dr. MORTON.—Whether repeated passages of gall-stones causing chronic incomplete obstruction of the intestinal common orifice of the bile and pancreatic ducts can be the cause of the cyst formation, or the gall-stone formation be simply secondary to a cyst of the pancreas (from any other cause), or whether the cyst and gall-stones are unrelated I cannot pretend to adjudicate. No pancreatic stone was found. I am indebted to Mr. Horrocks for permission to publish this case and to Dr. Chapman for his assistance in the physical and chemical examinations.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Non-calcifying Plastic Osteitis.—Report on a Museum Specimen of Malignant Enchondroma of the Testicle.—Exhibition of Specimens.

A MEETING of this society was held on Jan. 19th, Mr. BUTLIN, the President, being in the chair.

Mr. BERNARD PITTS and Mr. S. G. SHATTOCK gave a detailed account of a very unusual case, for which they ventured to propose the name of Non-calcifying Plastic Osteitis. A thin and careworn woman, aged thirty-nine years, was admitted to St. Thomas's Hospital wearing an apparatus for a deformity of the right leg. She could only walk with difficulty and great pain. At the age of thirty-one years she had a fall and struck her right leg. Three months later the knee became stiff and painful; two years later, after a confinement, the knee became much worse. She had since been a patient at several hospitals. On examination the leg was found to be very wasted and flexed at the knee almost to a right angle. There was an apparent displacement backwards of the tibia and fibula. The upper third of the tibia was exceedingly tender, and distinct mobility was detected at what appeared to be the junction of the epiphysis and shaft; this movement was

Hosted by Google

without crepitus, but attended with great pain. The knee-jerks of the left leg were greatly increased, but no rigidity or ankle clonus was present. On account of the pain and discomfort amputation was performed in November, 1895. The patient recovered, and at the present time is in fairly good health. No other bones of the body were diseased. The upper half of the tibia had undergone a uniform transformation into a minutely cancellous, bone-like substance, so devoid of earthy salts that the bone itself was as pliable as indiarubber. Precisely similar tissue completely filled the medullary cavity. Microscopic sections were cut quite readily without artificial decalcification. They were stained with carmine and hæmatoxylin. The trabeculæ, which took the carmine stain like bone decalcified artificially, were surrounded with a definite layer of osteoblasts, the amount of re-absorption by osteoclasts being quite insignificant compared with that of new production. The spaces between the trabeculæ were everywhere occupied by a highly cellular connective tissue, which contained but few leucocytes. The sections of the nerves in the periosteum exhibited a perfectly normal structure. In the gross the anatomical result was like that presented by the calvaria in osteitis deformans before sclerosis had supervened, but differed in the absence of calcification. The tissue most closely resembled the uncalcified osteoid tissue seen in rickets around the shafts or upon the flat bones. Rickets in this case was excluded by reason of the clinical differences, the strict localisation of the disease to the upper half of the bone, the filling of the medullary cavity with the osteoid tissue, &c. Mr. Pitts and Mr. Shattock regarded the condition as an osteitis in the sense in which any chronic osteoplastic process could be called inflammatory. Following Virchow's teaching, Recklinghausen, in his recent monograph on fibrous or deforming osteitis, had adopted the view which took osteomalacia to be an inflammatory lesion. In this disease, however, the amount of bone-production was conspicuous by its absence; the osteitis was almost completely aplastic; moreover, the decalcification and metaplasia of the decalcifying bone into fibrous tissue seen in osteomalacia were absent in the specimen under consideration. Recklinghausen had adopted the term osteitis fibrosa as a synonym for osteitis deformans for the reason that in certain cases an obvious amount of fibrous tissue may be met with in the bones, but in none had want of calcification been observed; moreover, there was no fibrous formation in the present specimen. The cases of frontal leontiasis recorded by Mr. Horsley exhibited an inter-trabecular formation of fibrous tissue, but the bone, again, was not uncalcified and the operations for its removal were conducted by means of the trephine and saw. Mr. Pitts and Mr. Shattock, in conclusion, found it impossible to class the specimen under the heading either of osteomalacia or osteitis deformans. The lesion was an osteitis occurring in the adult of a pronounced plastic character, but unaccompanied with calcification of the new osseous tissue, and in all this was so remarkable that they had proposed the term "non-calcifying plastic osteitis," thinking that its etiology might prove to be different from that underlying other better known and commoner anatomical conditions.—Dr. KANTHACK did not think that the possibility of new growth had been satisfactorily excluded. He had found an osteoblastic layer similar to that described almost always present in the new bone of osteoid sarcomas, and here also calcareous salts were often absent. He had seen cases of sarcoma of bone, with secondary growths elsewhere, having macroscopic and microscopic appearances just like those in this case. The long history was against the theory of the change being due to a growth, but it was possible that secondary growths might yet occur.—Mr. SPENCER suggested that possibly it might be a case of new growth arising from the white cells of marrow—"myeloma" or lymph-adenoma of bone. Several of these cases recorded had occurred as single tumours, and had lasted as long as in the present case without giving rise to secondary growths, and in several an injury appeared to have been the exciting cause.—The PRESIDENT hoped that Mr. Pitts and Mr. Shattock would place their case under the heading osteitis deformans. He thought that the specimen illustrated a stage in that disease at which the bones were plastic and the deformity took place. The tumour origin of osteitis deformans had been suggested some years ago by Dr. Goodhart and others, but unless secondary growths should occur there was no evidence for regarding this specimen as a tumour.—Mr. PITTS, in reply, said he did not believe there was a growth. The name was provisional. He regarded the condition as most closely allied to osteitis deformans.—Mr. SHATTOCK also thought there was no evidence of growth. This case differed from the other conditions which had been mentioned, the softness being due here, not to decalcification of pre-existing bone, but to new formation of uncalcified bone.

Dr. KANTHACK and Mr. T. STRANGEWAYS PIGG gave the result of their recent examination of a Specimen in the Museum of St. Bartholomew's Hospital which was described forty years ago by Sir James Paget as one of Enchondroma of the Testicle. The specimens showed to the naked eye a cartilaginous looking tumour of the testis, with growth extending along the spermatic cord and the pampiniform plexus and extending into the inferior vena cava, where there was a mass of new growth projecting into the lumen. Sir James Paget found numerous secondary cartilaginous growths in the lungs, and an intra-vascular growth in a branch of the pulmonary artery. The lymphatic glands were not enlarged. Mr. Butlin in his work on Sarcoma had thrown doubt on whether this were a case of enchondroma. The result of the examination by Dr. Kanthack and Mr. Pigg left no doubt in their minds that this was a columnar-celled carcinoma in which metaplasia of the fibrous tissue into cartilage had taken place, this chondrification being in places so extensive as quite to mask the carcinomatous nature of the tumour. The tumour had extended by the veins and not, as originally described, by the lymphatics. Sections through the pampiniform plexus showed that the lumen of the veins was filled by a fibrous stroma containing alveoli lined by columnar epithelium. There were also (as in other cases of carcinoma of the testis recently described by Dr. Kanthack and Mr. Pigg) masses of squamous-looking epithelium with concentrically arranged cell nests. The fibrous stroma contained much cartilage, usually in round masses, but in places showing gradual transition from fibrous tissue. In some parts the tissue was loose and almost myxomatous in character. In the testis cartilage was predominant, but the existence of columnar epithelium in alveoli could be traced. The occurrence of cartilage in carcinomata and their secondary deposits had been described by Virchow and figured by Ziegler. It illustrated the importance of the stroma as well as the epithelial elements of a malignant growth. Dr. Kanthack and Mr. Pigg referred to the remarkable acumen and accuracy displayed by Sir James Paget in his original description notwithstanding the imperfections of histological technique at his disposal.—The PRESIDENT thought the main point was the malignancy of the tumour. He had been led to doubt its innocence both from the naked-eye appearance of the tumour and from Sir James Paget's description, but had not till now seen sections. He agreed that it was a carcinoma.—Dr. SNOW considered that from the variety of tissues present the specimen should be regarded as a "blastoma" arising from fœtal residua.—Mr. BOWLBY thought the demonstration clearly showed the tumour to be a carcinoma with chondrification of the matrix. The absence of involvement of the lymphatic glands was exceptional. The existence of columnar cells was noted by Sir J. Paget; but, probably owing to the imperfect histological methods of the day, their arrangement and significance had escaped him.

The following card specimens were shown:—

Mr. PERCY PATON: (1) Fracture of the Radius and Ulna at the Epiphysis; and (2) Prævertebral Abscess.

Dr. TURNEY: Intra-pericardial Aortic Aneurysm communicating with the Superior Vena Cava.

HUNTERIAN SOCIETY.

Exhibition of Specimens.

AN ordinary pathological meeting of this society was held on Jan. 13th, the President, Dr. G. E. HERMAN, being in the chair.

Mr. T. H. OPENSHAW showed a Solid Ovarian Tumour—a small-celled sarcoma—removed from a woman who had been confined ten days before admission to hospital. Dr. Herman examined the patient and diagnosed a sarcomatous tumour. There was a large amount of ascitic fluid in the abdomen. The uterine cavity was three and a half inches in length. The interesting points of the case were: (1) the size of the tumour—7½ lb.; (2) its solidity; and (3) the pedicle was twisted.—Dr. HERMAN spoke on the question of recurrence of sarcomatous tumours of the ovary and said that it was by no means certain—Mr. TARGETT alluded to the fact that

Hosted by Google

fibroma of the uterus was sometimes associated with ascites.—Dr. F. J. SMITH alluded to two cases of sarcoma of the omentum, one with much ascites which simulated extra-uterine pregnancy, and the second a solid growth with but little ascites.

Mr. OPENSHAW then brought before the society the leg and foot of a boy aged fifteen years. At the age of seven years he had Acute Periostitis of the Lower Half of the Tibia. In the specimen part of the shaft of the tibia had not been reproduced, while the fibula had continued to grow. The inferior tibio-fibular articulation was very loose and, owing to the absence of part of the shaft of the tibia, he could twist the foot in any direction.—Mr. TUBBY, in speaking to Mr. Openshaw's point on the propriety of waiting before removing the dead bone, thought that it was better to remove the sequestrum early and to maintain the cavity of the periosteum by stuffing it with gauze.—Mr. TARGETT alluded to some cases of congenital absence of the tibia simulating the condition seen in Mr. Openshaw's case.

Mr. TARGETT presented two specimens of Malignant Growth of the Uterus: one of villous character and the second a columnar-celled carcinoma.—Dr. HERMAN remarked that it was unusual for a uterus with malignant growth of the body to be of such size as the specimen Mr. Targett had described. Dr. Herman thought that in cancer of the body of the uterus the microscope by itself was not always trustworthy from a diagnostic point of view.

Dr. J. H. SEQUEIRA showed a specimen of Secondary Carcinoma of the Spleen, the primary growth being in the uterus.—Dr. HERMAN remarked that cases of cancer of the body of the uterus do not frequently (10 per cent.) give rise to secondary growths in distant organs.—Dr. F. J. SMITH remarked upon the comparative infrequency of secondary splenic growths.

Dr. SEQUEIRA also exhibited the Head of a Femur from a case of Rheumatoid Arthritis in a man aged fifty-six years. In this instance the ligamentum teres had entirely disappeared and there was lipping of the femoral head and acetabulum.—Dr. SMITH asked if the ligamentum teres were ever congenitally absent, and Mr. OPENSHAW remarked its absence in congenital dislocation of the hip.

Dr. F. J. SMITH brought forward a specimen of large White Kidney from a boy, aged fifteen years, who had been ill for only three weeks. The interest of the specimen lay in the fact that it was in opposition to the generally received teaching of the essentially chronic nature of large white kidney. The case was also of interest from a life insurance point of view, as a life might be accepted and then develop renal symptoms shortly afterwards and a large white kidney be found post mortem.—Dr. ARTHUR DAVIES spoke on the points of cyclical albuminuria and life assurance.—Dr. HERMAN said that he was much interested in the discussion, as it was closely connected with puerperal eclampsia.

Dr. SMITH also showed the Lungs and Trachea from a boy aged nine years who was brought into the London Hospital dyspnœic and moribund. Tracheotomy was performed unsuccessfully. At the necropsy an aneurysm of the descending aorta was found.

BRITISH GYNÆCOLOGICAL SOCIETY.

Annual Meeting.—Election of Officers.—Presentation of Reports.—President's Address.—Exhibition of Specimens.—Pan-Hysterectomy after Clamp Operation.

THE annual meeting of this society was held on Jan. 14th, Dr. CLEMENT GODSON, President, being in the chair.

The ballot was taken for the election of officers for the ensuing year, and the following were elected:—Honorary President: Dr. R. Barnes. President: Professor A. W. Mayo Robson. Vice-Presidents: Dr. G. G. Bantock, Dr. C. H. Bennett, Professor J. W. Byers, Dr. A. E. Cordes (Geneva), Dr. G. Elder, Dr. H. Macnaughton Jones, Dr. Leith Napier (Adelaide), Professor W. L. Reid, Dr. C. H. F. Routh, Dr. F. F. Schacht, Dr. W. Travers, and Professor Hector Treub (Amsterdam). Treasurer: Dr. J. A. Mansell Moullin. Council: Mr. W. Armstrong, Dr. Dudley W. Buxton, Mr. T. Kilner Clarke, Mr. E. Tenison Collins, Mr. W. Dingley, Dr. A. Donald, Dr. F. Edge, Dr. C. Godson, Dr. F. N. Haultain, Dr. W. Balls Headley (Melbourne), Dr. P. L. Hebert, Mr. R. A. Hodgson, Mr. F. Bowreman Jessett, Mr. Skene Keith, Dr. Henry Lewis, Dr. R. Marsden Low, Dr. J. J. Macan, Mr. Christopher Martin, Dr. James Oliver, Mr. H. W. F. Powell, Dr. T. Savage, Professor A. J. Smith, Dr. D. Thomson, and Dr. W. S. Wyman. Editor of Journal: Dr. F. F. Schacht. Hon. Secretaries: Dr. John Shaw and Dr. George E. Keith.

The Treasurer and the Editor of the Journal presented their reports.

The PRESIDENT then delivered his Valedictory Address, which will be found in full on p. 221.

Mr. JESSETT moved, and Mr. J. W. TAYLOR seconded, that a hearty vote of thanks be given to the retiring President for his excellent address, and that he be asked to allow it to be printed in the Journal of the society.

Dr. H. M. MACNAUGHTON-JONES showed for Dr. MACNAUGHTON-JONES a Microscopic Section of a Specimen of Deciduoma Malignum.

Dr. F. A. PURCELL showed a new form of Intestinal Clamp for Compressing a Colotomy Spur.

Mr. J. W. TAYLOR (Birmingham) read a communication on Two Cases of Pan-Hysterectomy after Previous Treatment by the Clamp Operation, and showed the specimens.—Mr. BOWREMAN JESSETT congratulated Mr. Taylor on his successful results and the society on the fact that for three or four years it had insisted that total extirpation was the best treatment for uterine myomata. By using the clamp, one or more myomata might be left behind and need a second operation, as in Mr. Taylor's second case. Kelly's operation was new to him, and this was the first time that it had been brought before the society. Probably the method adopted by Mr. Taylor was the only one that could have been used in that particular case. They had to thank Mr. Taylor for bringing these cases before them; they could not see too many of such specimens, and it was well to have a variety of methods available to choose from.—Dr. HEYWOOD SMITH said that from the description Kelly's method seemed easy, but it appeared to him doubtful whether it could be used in the case of a large tumour blocking up the pelvis, as it would be difficult to tilt the cervix sufficiently to get at it.—Mr. J. F. JORDAN (Birmingham) had had the good fortune to assist Mr. Taylor in his case of Doyen's operation. He had not himself used this method. In the three cases of hysterectomy which he had performed he had used Mr. Jessett's method with successful results. Speaking as one of the younger gynæcologists he thought they were fortunate in that the battle as to the best method of dealing with uterine myomata had been nearly fought out. To him complete extirpation seemed the best treatment. Of course they had to consider the mortality of each procedure; and so far it would seem that the mortality after total extirpation was not greater than that of other methods, but would rather prove to be less. The drawback of Doyen's method was that it did not appear to be available for cases of myomata blocking up the pelvis; but he was still in doubt as to the manner in which such cases should be dealt with.—Dr. F. A. PURCELL observed that Mr. Taylor's communication was an extension of the discussion on hysterectomy which they had had at the last meeting. For his part, he did not yet feel bold enough to strip the sides of a myoma and leave the vessels untied till after they had been secured by an assistant. An allusion had been made to large tumours blocking up the pelvis; in such a case he had adopted the method of separating the broad ligament on each side, slicing the tumour across, then dissecting the remaining portion out of the broad ligaments, and so completing the total extirpation.—Dr. BEDFORD FENWICK asked for information on two practical points: (1) the time occupied by each operation, and (2) the time required for separation of the ligatures. The society was to be congratulated on these cases; there was no doubt that they must come ultimately to adopt an intra-peritoneal method and they were fast advancing in this direction.—Mr. TAYLOR, in reply, said that such operations as he had described must necessarily take some time, varying from a little under one hour to one and a half hours. A careful study of the specimen removed by Kelly's method would answer the questions that might be raised about it. The size of a tumour in the pelvis was necessarily limited by the size of the pelvis itself, and if one side remained healthy and accessible the size of the remainder would probably not matter much. The worst cases they had to deal with were such as Mr. Jordan had referred to, where the pelvis was blocked on both sides; in such a case Doyen's method might be useful. It was also especially applicable to those cases in which the connexions between growth and bladder could not be properly attacked from above.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Specimens and Cases.—Asthma and Hay Fever of Nasal Origin.—Undescended Testicle.

A MEETING of this society was held on Jan. 12th, the President, Mr. G. CARTER, being in the chair.

Dr. EURICH showed a series of sections illustrating the Development of the various tracts of the Spinal Cord and Medulla Oblongata. He pointed out that on section of the cord degeneration of tracts occurred in the order of development.

Dr. A. BRONNER showed a case of Internal Strabismus and advocated advancement of the external rectus, combined with tenotomy of the internal rectus, as opposed to simple tenotomy, in treatment of these cases.—Dr. Bronner also showed cases of Iritis, Glaucoma, and of Interstitial Keratitis, and remarked on the complete recovery which took place, under treatment, of cases of the latter affection due to syphilis.

Dr. A. BRONNER then read a paper on Cases of Asthma and Hay Fever of Nasal Origin. He pointed out that the symptoms might be: (1) a direct result of nasal obstruction; (2) the result of irritation of the endings of the fifth nerve by polypus, by atrophy or hypertrophy of the nasal mucous membrane, by foreign bodies, or by necrosis of the bones of the nose; (3) the outcome of a central neurosis, in which cases the application of the cautery gave relief by acting as a counter-irritant. Dr. Bronner gave details of several inveterate cases of asthma and hay fever cured by treatment directed to the unasal cavity. He advocated examination of the nose in all s ch cases and the removal of any abnormal condition if present.

Dr. JOHNSTONE CAMPBELL showed the Stomach from a case of Diffuse Cancer of that organ which had invaded the head of the Pancreas. The stomach presented great contraction of its cavity. The symptoms during life were rapid wasting, constipation, and vomiting coming on after a few mouthfuls of food had been swallowed. There was no glycosuria.

Dr. C. W. CHAPMAN showed a case of Perforated Ulcer of the Duodenum causing death after only thirty-six hours' illness. There was no history of previous attacks and the patient had gone to his work up to the time of the fatal seizure.—Dr. Chapman also showed a case of Peripheral Neuritis affecting the legs, which was said to be the result of bandaging the limbs in the treatment of severe secondary hæmorrhage from an operation wound. There was no history of syphilis or of alcoholic excess.

Dr. CAREW WEBB showed a case of Peripheral Neuritis coming on after chorea, which latter affection had been treated with arsenic. The patient was a girl eight years old. Eight months previously she had been treated with arsenic for one month and had obtained relief. Three months ago the chorea recurred. Six minims of liquor arsenicalis were given three times a day, and this was increased in the course of ten days to twelve and a half minims thrice daily. After three weeks she was discharged well as to the chorea. She returned in a week unable to walk alone. She had wrist-drop and foot-drop, with loss of sensation over the median nerve area. The knee-jerks with superficial and deep reflexes were absent. No symptoms of arsenical intoxication were present except a slight attack of vomiting lasting one day. There had been slight improvement under treatment.—Dr. GOYDER suggested a rheumatic origin for the neuritis.—Dr. KERR, Dr. JOHNSON, and Dr. MITCHELL discussed the case.

Mr. WILLIAM HORROCKS read a paper on Undescended Testicle. Among the causes mentioned were: (1) intra-uterine peritonitis giving rise to adhesions between the testicle and the cæcum or small intestine; (2) contraction of the external abdominal ring owing to over-development of the transverse fibres; (3) incomplete development of the inguinal canal; (4) absence of the gubernaculum testis; (5) excessive action of the cremaster, due to reflex irritation (phimosis, &c.); (6) undue shortness of the vas deferens or of the vessels of the cord; and (7) long mesorchium, allowing the testicle to wander freely in the abdominal cavity. He mentioned in connexion with the first cause that adhesions to the cæcum may not prevent descent of the testicle, but that the cæcum may descend with the testicle and give rise to a hernia with an imperfect peritoneal covering. With regard to the functional activity of an undescended testicle, it was shown that it was not necessarily sterile, as Curling asserted, but that its action depended less on its position than on its freedom from inflammatory attacks following injuries. The complications of undescended testicle were: (1) inflammation, especially in the inguinal position; (2) special liability to malignant disease, more particularly in testicles lying in the inguinal canal; and (3) hernia, the bowel being sometimes adherent to the testis. Treatment by truss was deprecated as worse than useless owing to the difficulty of getting downward pressure, while at the same time injurious pressure was exerted on the testicle and on the vessels of the cord. Treatment by transplantation and by daily downward manipulation was said to be useless. Operation by drawing down and suturing the testicle to the scrotum, obliterating the processus vaginalis, and suturing the ring was not successful when the cord was too short, being followed either by re-ascent of the testicle or by its atrophy. Dissection of the globus minor from the testicle in order to give greater length to the cord was tried in one case, but the testicle atrophied. Assuming the testicle to be not liable in any given case to attacks of inflammation it was recommended that no operation be performed before the age of thirteen years, as up to that age there was a prospect of the testicle descending normally. In the meantime phimosis or any condition liable to cause reflex action of the cremaster might be dealt with. A hernia co-existing with the undescended testis must be dealt with on ordinary lines, the liability of the presence of the cæcum with an imperfect covering being borne in mind.—Dr. ALTHORP pointed out the intimate relations in position between the cæcum and testis during development.—Dr. LODGE mentioned a case of cryptorchism in which there was perfect functional activity of the testicle.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—Agraphia and the Question of the Existence of a Special Graphic Centre in the Cerebrum.

A MEETING of this society was held on Jan. 13th, the President, Dr. ARGYLL ROBERTSON, being in the chair.

Dr. AFFLECK showed a young woman who had been admitted to the infirmary with symptoms of Cerebral Gumma. There was a clear history of syphilis. The third nerve was the first to be affected, after which followed the fourth and sixth nerves. Under treatment the affection of these various nerves had passed off, so that after about two months' treatment there was only a little paresis left.

Dr. MILES showed a man whose Tongue he had removed for Malignant Disease. He had gained much room by the removal of two teeth and the incision for removal of enlarged glands under the jaw was taken advantage of for ligaturing the lingual arteries and thus preventing hæmorrhage. He also showed a boy on whom he had operated by Kocher's method with considerable success for Double Equino-varus.

Dr. MACGILLIVRAY showed a Calculus removed by Nephrotomy from the pelvis of the left Kidney, and the patient from whom it had been removed. He also showed a Kidney from a successful case of Nephrectomy; the kidney was cystic and collapsed, the result of a calculus which lay in the ureter at its junction with the pelvis.

Dr. WILLIAM ELDER then read a paper on Agraphia and the Question of the Existence of a Special Graphic Centre in the Cerebrum. He set himself to inquire whether there was a type of asphasia which could be called graphic aphasia. He referred to the four great types of aphasia—auditory, visual, motor, and conduction. He also referred to Wernicke's sub-divisions of sub-cortical, cortical, and trans-cortical, and that there might be three sub-divisions of any of the first three main groups. He then indicated the graphic symptoms in each variety of aphasia: in the auditory form there was paragraphia and also agraphia to dictation, but the patient was usually able to copy. In visual aphasia the patient can write voluntarily and to dictation, but there were disturbances of copying power. In motor aphasia when subcortical there is no disturbance of writing, when cortical there is loss of voluntary writing and also writing to dictation. In conduction-aphasia there is power of writing voluntarily and to dictation, but there is paragraphia. He

Hosted by Google

then examined the question of whether there was evidence to show that there have been cases of agraphia other than those due to lesions of the speech centres and the fibres connected with them, and concluded that no conclusive evidence existed as to the existence of a separate graphic centre. Not satisfied with this he took up the consideration of the question from a theoretical study of writing. He argued that in writing the word-seeing centre guided the hand movements, but while this was so he thought the memories of the fine movements and peculiar shapes were stored in a special centre, and that the fine movements required in many expert manipulations were thus stored. Such a centre was not necessarily a large one for it stored only the graphic image of letters, not of words; the words being combined by means of the psycho-motor speech centres and the auditory word centre. The power of forming letters by the left hand he held was different altogether from the expert writing of the right hand, and if the left hand were guided by the centre in the left hemisphere the writing would be "mirror-writing." He had examined a number of adults and children and found that a certain proportion of them when asked to write with the left hand did it in "mirror" fashion. He gave details of an interesting case of motor aphasia with agraphia in which the former was recovered from while the agraphia was persistent. — In the discussion on this paper Dr. BYROM BRAMWELL argued against the existence of a special graphic centre.—Dr. IRELAND considered that there was too great a desire to sub-divide the cerebral cortex when the function of the cortex as a whole ought to be more regarded.—Dr. CLOUSTON thought a presumption had been established for a special centre, but that if writing had a special centre other movements must also have centres.—Dr. MACPHERSON questioned the practical value of localising such a centre even if it existed.

EDINBURGH OBSTETRICAL SOCIETY.

Exhibition of Specimens.—Hæmorrhage from Rupture through a Mucous Cyst.—Retention of the Menstrual Fluid.—Extra-uterine Gestation.

A MEETING of this society was held on Jan. 14th, Professor SIMPSON, Vice-President, being in the chair.

Dr. J. A. C. KYNOCH (Dundee) showed a Tumour of the Right Kidney which he had removed by abdominal nephrectomy from an infant sixteen months old. The tumour was about the size of a large lemon and grew from the posterior part of the kidney. All that remained of the kidney substance was a small portion on the summit and another part spread as a capsule over the tumour. The tumour microscopically was found to be adenomatous, consisting of alveoli lined by columnar epithelium with a large amount of fibrous tissue. The child is now (six weeks after operation) quite recovered and well.

Profe sor SIMPSON exhibited an Anencephalic Fœtus with Spina Bifida which had ruptured during intra-uterine life. He also exhibited a Fœtus showing so-called Fœtal Ascites, with lymph deposit on the surface of the liver and pleural effusion. He also showed a Colloid Tumour of the Ovary, the cysts being very small with thin walls; one had burst into the peritoneum before removal; the other ovary was the seat of a similar tumour of small size.

Dr. KEPPIE PATERSON showed a Genealogical Table tracing the occurrence of twins to the male progenitors. In a family of three generations there were nine confinements, and six of these were twin births; one member had twins with both his first and second wife. The table was from Professor Winckel's clinic in Munich.

Dr. R. C. BUIST (Dundee) read a paper on a case of Hæmorrhage from Rupture through a Mucous Cyst. The patient was eighty-one years old and had suffered from complete prolapse of the uterus for many years. Serious hæmorrhage had occurred, and when examined blood was found oozing from the inner side of an irregular protuberance 1 c.m. high close to the os uteri. On grasping it with forceps the mass came away, leaving a base from which blood oozed freely. The bleeding was controlled by a couple of silkworm gut sutures. The case was evidently one where the passive congestion due to the prolapse had produced hæmorrhage into a mucous cyst and secondary external hæmorrhage from rupture of the cyst wall.

Dr. LAMOND LACKIE read a paper on Retention of Menstrual Fluid in one half of a Double Uterus, and recorded a case in which menstruation occurred normally from one half of a uterus septus, while an intermittent hæmatometra recurred in the other. The patient was twenty-four years of age, unmarried, and had menstruated regularly since the age of sixteen years, but she complained of a pain in the right side and of a hæmorrhagic discharge which came on every four months and continued for three weeks. The pain in the side was relieved for a time by the flow, but gradually came on again and increased till it was again relieved after four months by the discharge. Further, she said that every month between two menstrual periods she suffered from an acute exacerbation of pain and felt as if she were about to menstruate, but there was no external sign of this. On examination there was felt a marked bulging in the right fornix and a distinct, well-defined tumour in the hypogastric and right iliac regions. The patient said that she had always observed a swelling in the right side before a hæmorrhage came on, and stated that it disappeared when the flow was established. She was kept under observation for some time, and ultimately the tumour was aspirated per vaginam in order to clear up the diagnosis. The fluid was found to be altered menstrual blood. Later, when the sac had once more filled up, an incision was made into it per vaginam and the cavity explored by a sound, when the diagnosis was easily confirmed. Bougies were then forced through the septum between the two halves at the level of the cervical canal, so as to establish free communication between both cavities. A drainage-tube was then inserted along the cervical canal and into the dilated half. The incision made through the lateral fornix was then stitched up. The patient's subsequent menstrual history was interesting; she menstruated every fortnight alternately from each half of the uterus. This was proved by the fact that every second time the fluid escaped entirely by the drainage-tube, which had been left protruding beyond the vulva. Dr. Lackie remarked that this alternate menstruation in some cases of double uterus had been observed by Emmet, Kussmaul, and others. The case was not one of "uterus bicornis," since clinically no sulcus could be felt between the two horns, but rather one of "uterus septus," in which one half had a very imperfect communication with the common cervical canal. It seemed to require considerable distension of the sac to force the small opening which must have existed, although at the time of operation it could not be discovered. Dr. Lackie then discussed the differential diagnosis, and in conclusion referred to the literature of the subject and appended a list of twenty-four cases to his paper. The mortality following the operation for relief of the condition was very high, being no less than 50 per cent.—Dr. HAULTAIN, Dr. BERRY HART, and others made remarks on the subject.

Dr. C. F. A. MOSS (Antananarivo) sent a paper on a case of Extra-uterine Gestation, which was communicated by Dr. BARBOUR. The patient was thirty-nine years of age and had been three times pregnant, the last ending in abortion fourteen years ago. The menstruation had been regular and normal till six months previously to her admission. The last flow was scanty and accompanied by much pain in the hypogastrium and rectum, so severe as to cause fainting. For four months she had little or no pain, but noticed an abdominal tumour, at first in the middle line, and afterwards passing over to the left side. From that time till her admission two months afterwards she suffered from attacks of pain, dysuria, and diarrhœa, with bloody stools. On examination a tumour was found occupying the lower abdominal region on the right side extending two inches above the umbilicus, rather lower on the left, and bulging into the flanks. Slight fœtal movements were felt and the fœtal heart could be heard. Per vaginam a bony mass could be felt bulging into the posterior vaginal wall close to the ostium vaginæ. The cervix was very high, and a mass resembling a slightly enlarged uterus was felt above the pubes. By the rectum the sagittal suture could be distinguished. There was difficulty in deciding between the diagnosis of an extra-uterine gestation or a retroverted gravid uterus. Three weeks after admission there was false labour with the passage of decidua, and she left hospital a fortnight later fairly strong and without pain. She afterwards returned complaining of intense abdominal pain and menorrhagia, and laparotomy was performed three months from the date of the false labour. The sac was found covered by peritoneum, there were slight

Hosted by Google

adhesions to the omentum, but none to the abdominal wall. The uterus was lying to the left and free from the sac. The sac was incised and its edges stitched to the parietal peritoneum. The right side of the sac was completely occupied by the placenta, which was dry and bloodless; the left side was occupied by a full time, but much shrivelled, female child. After extraction of the child the placenta was easily detached and removed. There was a rent in the posterior wall of the sac through which the bowel and omentum had prolapsed, the latter being adherent to the placenta. A small sac was found in the lower part of the large sac. The cavity was washed out, clots were removed, and a drainage tube was inserted. The patient made an excellent recovery. Dr. Moss has seen five other such cases in Antananarivo.

Dr. FREELAND BARBOUR read a paper on Laparotomy for a five months' Extra-uterine Gestation. The patient was thirty-two years of age and had one full-time child and two miscarriages subsequently. Early in the history of this pregnancy she had suffered from sudden attacks of nausea, pain, and vomiting. A tumour showed itself in the right iliac region and gradually increased in size. Fœtal movements were felt for about three weeks, but these ceased after an attack of giddiness, accompanied by vomiting, and followed afterwards by unconsciousness. A day or two after this a pale bloody discharge escaped from the vagina containing shreds like skin. She was confined to bed for some weeks and suffered from exacerbations of the pain, accompanied by vomiting. There was one other uterine discharge. On removal to hospital a large abdominal tumour was found, irregular in outline and reaching to within about one inch of the umbilicus; it was solid at some points and cystic at others. On operation the tumour was found to be covered by peritoneum, but lifted up in the right iliac fossa, while inferiorly it extended into the pelvis. The sac was stitched to the abdominal incision. On opening the sac firm, dry blood-clots were encountered, and from the lower part lumps of dry and bloodless placental tissue were removed. A mummified fœtus twelve and a half inches long was removed from the upper part of the sac with some difficulty; it was lying in a large diverticulum, which extended up into the right hypochondrium. The secondary sac seemed to be intra-peritoneal. The sac was washed out; there was a little bleeding, which was easily controlled. Both cavities were packed with iodoform gauze. The patient recovered satisfactorily. In discussing the question of the best time for operating it seemed to be generally accepted in the later months if the fœtus is dead to wait for a certain amount of atrophy of the placenta to take place; the question of interference in the interest of a living fœtus was still *sub lite*. There is also a difference of opinion with regard to the desirability of immediate operation in cases of rupture during the early months. Dr. Barbour referred to the literature of different cases operated on in the later months and discussed the risk of hæmorrhage from the placenta during operation, as well as the subject of stitching of the sac to the abdominal wall. Professor SIMPSON remarked that if it were possible it was better to see to the peritoneum of the abdominal wall and so diminish risk of peritoneal infection.—Dr. BERRY HART stated that the sac in the extra-uterine gestation was in part extra-peritoneal and with a peritoneal periphery; if the latter portion were opened into it was better to stitch to the abdominal walls, but if the peritoneum was not opened into it was not necessary. The sickness and vomiting occurring with the internal hæmorrhage were evidently due to the resulting cerebral anæmia. He had not experienced any trouble from hæmorrhage in operating on these cases, even if the placenta were cut into, as he had found plugging with iodoform gauze sufficient to control it; if there had been bleeding the tampon could be inserted and the placenta left to be dealt with at a subsequent operation a few days later.—Dr. HAULTAIN remarked that the question of stitching before opening into the sac was a question of diagnosis. If the child were alive and the placenta were opened into it might be difficult to control the hæmorrhage, and he instanced a case where the bleeding could only be controlled by pressure from the outside of the sac at its base; if the sac had been stitched to the abdominal wall at the beginning of the operation there would have been trouble and delay in dealing with the hæmorrhage.—Dr. BARBOUR, in reply, stated that in all advanced cases it was more likely that the sac would be opened through the peritoneum and not through the cellular tissue or extra-peritoneally

Reviews and Notices of Books.

An American Text-book of Applied Therapeutics, for the Use of Practitioners and Students. Edited by J. C. WILSON, M.D., assisted by A. ESHNER, M.D. London: The Rebman Publishing Company. 1896. Price 42*s*.

THIS handsome volume, which in the style of its production leaves little to be desired, forms an excellent example of the now prevalent practice of coöperative authorship. In a subject so vast as that of the treatment of disease it is certainly of advantage to enlist the services of many contributors if the work is to speak with authority and command respect. It is barely possible for a single pen to adequately compass the field or for a single physician, however able, to make himself acquainted with the extensive literature of the subject. The editor of the work before us has been fortunate in securing the services of many well-known American physicians to assist him in the task, together with two contributors from outside the American Continent. These are Professor Laveran, who writes on Malarial Fevers, and the late Dr. Beaven Rake, whose admirable and careful work on Leprosy is here supplemented by what was, we suppose, the last writing of a gifted and able observer. The work of editorial revision has evidently been carefully exercised, for there seems to be rather more uniformity of treatment of the subjects than mostly occurs in compendia of this description. In one respect, indeed, we are prejudiced enough to regard this exercise of editorial privilege with regret. It is that the editor has adopted the "new spelling," which is growing in fashion in American medical literature, but for which we are ourselves unable to assume any enthusiasm. The plan of the work is one which will commend itself to readers, for it takes them systematically through individual diseases and groups of diseases, instead of adopting the less attractive and often wearisome method of the ordinary therapeutic text-book.

Avoiding the discussion of general principles and hygiene, the book opens with articles upon the Treatment of Acute poisoning and on the Resuscitation of the Apparently Drowned, by Dr. J. E. Atkinson of Maryland. Next follows a contribution by Dr. Victor C. Vaughan of the University of Michigan upon the interesting topic of Food Infection. He gives a very good account of ptomaine poisoning, ergotism, and other forms of intoxication from the consumption of articles of diet. We would especially draw attention to the excellent descript on of the Opium Habit and Morphinism given by Dr. Carl Frese of Philadelphia, and we note his preference for the treatment of this vice by the "rapid gradual" method of Erlenmeyer to the more sudden withdrawal of the drug, which, if effectual, is only to be attempted with some risk. He expresses his opinion that these cases are best treated in institutions, but he does not speak very hopefully of permanent results being obtained. Other "drug habits" also receive notice. Alcoholism is dealt with by Dr. R. Edes who, we observe, considers that chloral and bromide of potassium are the most efficient sedatives in the treatment of delirium tremens. Passing to the infective diseases, the article on Diphtheria by Dr. W. Northrup may be cited as being fairly comprehensive and up-to-date. The impossibility of thorough disinfection of the tonsils and naso-pharynx by injections and sprays is frankly recognised, but useful hints are given as to the most effective means of carrying out in the child this essential, and not wholly ineffectual, line of treatment. In dealing with laryngeal diphtheria, much space is devoted to the subject of intubation, for which English practitioners will be grateful. Dr. Northrup considers that (in skilful hands) intubation is much to be preferred to tracheotomy, and it is doubtless with the view of gaining fuller recognition of its merits that

Hosted by Google

he has been careful to describe the method in detail, whereas but small space is given to tracheotomy. The question of antitoxin is regarded favourably and is mainly discussed in a notice of a report by Professor Welch. The Exanthemata are dealt with in a single article by Dr. G. Dock of Michigan; and it is interesting to observe how in these diseases the value of bathing is coming to be recognised and full justice being done to Dr. Currie of Liverpool, the pioneer in this line of treatment. This subject also receives extended notice at the hands of Dr. J. C. Wilson in his very excellent article on Enteric Fever. The efficacy of the routine treatment of this disease by bathing has been demonstrated to Dr. Wilson's satisfaction in the wards of the German Hospital at Philadelphia, where the practice has been in vogue since 1890. The studies of Professor Osler of Baltimore in the same direction are familiar to all, but we hardly think sufficient credit has been given by our American cousins to the work done in this subject in England ten or fifteen years ago. It was Dr. Cayley who in his Croonian Lectures before the Royal College of Physicians of London first demonstrated in this country the value of the treatment introduced by Brand, and subsequently adopted with much enthusiasm by Dr. Glenard of Lyons, after witnessing its results when a prisoner of war in Germany in 1870. Although much prominence is given to this treatment, Dr. Wilson covers the whole ground of the course and complications of enteric fever in a manner which is as attractive as it is scientific. He also writes on typhus fever, relapsing fever, and cerebro-spinal meningitis. To Dr. E. O. Shakespeare has been assigned the subject of Asiatic Cholera or "Cholera Infectiosa," as it is termed, and it is notable for the conviction he possesses of the efficacy of the methods of protective inoculation introduced by Ferran and the more recently accepted method of M. Haffkine. The following passage clearly expresses what the writer feels on this question:—

"The destructive severity of cholera epidemics in India is decidedly increasing. During the eight years from 1878 to 1885 inclusive there were in India upwards of 2,000,000 deaths from cholera; during the seven years from 1886 to 1892 inclusive there were in the same country upwards of 3,000,000 deaths from the same disease. This appalling increase of an already frightful mortality due to cholera furnishes the most positive proof that, whatever the official sanitarians connected with the Government of India may assert in international sanitary congresses and elsewhere in laudation of the prophylactic measures said to be enforced in India, at great expense, for the limitation of the movements of cholera there, they are utterly incapable of accomplishing the object. In view of the ineradicable influences of caste and antiquated, abominable domestic customs universally prevalent among the natives of India, one personally familiar with the nearly absolute lack of sanitation among the native populations of Hindostan must be visionary indeed if he can even dream of ever remotely approaching the effectual restriction of cholera epidemics in that country by means of the mode of general prophylaxis in vogue there in the past and at present."—P. 276.

And he goes on to say that he is convinced, from a study of the statistics of cholera in Spain in 1885, that the only feasible plan of restricting the disease is by preventive inoculation such as was practised by Ferran in the villages of that country, the insanitary surroundings of which vie in degree with those of India. In the actual treatment of an attack of cholera stress is laid upon the advantages of lavage of the stomach and the method of enteroclysis with solutions of tannin and opium as practised by Cantani; whilst in the stage of collapse the subcutaneous injection of salt-solution (hypodermoclysis) is recommended. There follow articles on Yellow Fever by Dr. J. Guitéras; on Anthrax, Hydrophobia, Glanders, and Tetanus by Dr. J. Chalmers Da Costa; and on Weil's Disease by Dr. A. Eshner. The subject of Croupous Pneumonia is treated by Dr. I. N. Danforth of Chicago, who, whilst recognising our powerlessness to control the course of the disease, yet shows to what extent relief may be afforded. He advises the practice of venesection in the early stage, provided that the subject is suitable for this procedure, and he deprecates the prescription of antipyretic drugs, but thinks cold affusion and sponging valuable. He does not, however, say much about the use of the ice-bag, and clearly regards all such measures of value only in the stage of hyperæmia, although to say that a considerable number of cases may be "arrested" in this stage strikes us as rather optimistic. He divides the rest of the treatment of the disease into that of the stage of consolidation, of the crisis, and of the period of resolution, and finally alludes to the antitoxin method of the Drs. Klemperer as not unlikely to constitute a great advance in the treatment of pneumonia.

The extensive and important subject of Tuberculosis is in the capable hands of Dr. J. T. Whitaker. This, the most formidable and ubiquitous of human infective disorders, has been the subject of numberless treatises and the object of many a vaunted panacea. The writer of the article has well succeeded in a task which must have involved much labour, and we could wish that space would permit of our presenting a summary of his essay. It must suffice to say that in pulmonary tuberculosis he regards creosote as the remedy which has most established itself, although it cannot be claimed to have any specific action, and as substitutes for it he describes the use of guaiacol, cinnamic acid, and other even less commonly prescribed drugs. Nor does he think that tuberculin should be wholly discarded, although he would limit its employment to incipient pulmonary cases and to glandular and osseous tuberculosis. Full details are given in systematic fashion of the symptomatic treatment of pulmonary tuberculosis, and there is a succinct account of the relative advantages of climatic resorts. The subject of Syphilis is discussed by Dr. Orville Horwitz and there is a somewhat elaborate article on Malarial Fevers by Professor Laveran, which is largely taken up with a minute analysis of the action of quinine and its congeners. Similarly, in dealing with Acute Rheumatism Dr. James Stewart enters fully, if less elaborately, into a discussion of the salicyl compounds, but admits that hitherto no satisfactory explanation of their *modus operandi* has been forthcoming. The value of cold bathing for treating the formidable complication of hyperpyrexia is insisted on, but it would have added to the interest of the subject had the writer discussed the prodromal symptoms which warn the physician of the onset of this condition. The treatment of chronic rheumatism is hardly sufficiently considered, and although it is, perhaps, pardonable to find no mention of the latest method—that of super-heated air—yet some place might have been found for a discussion of the dietetic measure—which certainly succeeds in some intractable cases—which goes by the name of the "Salisbury treatment." The same writer has articles on Gout, Rheumatoid Arthritis, and on Rickets, and we confess to some disappointment in the perusal of the last named, which affords scope for much wider treatment. No allusion is made to "scurvy rickets" either here or under the head of scurvy. Passing to the article upon Diseases of the Stomach, by Dr. C. G. Stockton, it may be said that the writer has endeavoured to treat the subject more scientifically than is the rule by considering first the functional disorders which are mostly grouped as "dyspepsia" under such heads as "hyperchloridia," "lactic-acid excess," "diminished acidity and anacidity," gastralgia, gastric hyperæsthesia, and other familiar symptomatic affections. It is impossible not to be conscious of the enterprise here shown; but as in practice the carrying out of this plan involves the constant use of direct testing of the gastric secretions it is difficult for the practitioner to pursue. In this regard, indeed, science has gone far beyond the capabilities of ordinary practice,

Hosted by Google

and it may even be questioned whether the results of the treatment of the great army of dyspeptics on these scientific principles has yielded more relief than is afforded by the old-fashioned, if blinder, ways. Nevertheless, any means whereby the therapeutist can attain greater certainty upon the condition which he endeavours to alleviate ought not to be lightly discarded even at the cost of some trouble to the practitioner and discomfort to the patient. And the treatment of "dyspepsia" has long been one of the stumbling-blocks of medicine. Diseases of the Intestine are discussed by Dr. W. W. Johnston, and Diseases of the Liver by Dr. W. C. Darney, whose account of the treatment of gall-stone calls for special commendation. We note that he is convinced of the value of large doses of olive oil as a means for procuring the passage of biliary calculi, and suggests that the mode of action is partly by increasing the flow of bile and partly by lubrication of the mouth of the ductus choledochus. The important subject of Infant Feeding as well as articles on the Digestive Disorders of Infancy and on Dentition are from the pen of Dr. E. Graham of Jeaffreson College, Philadelphia. Amongst the remaining articles we may note especially that on Diseases of the Pleura, by Dr. A. L. Mason of Harvard University. In this article the measures of treatment are preceded by a brief account of the symptoms of the diseases. The indications for paracentesis are discussed with discrimination, and the methods of operating in serous and purulent effusions succinctly described. Instructive illustrations of the conditions in pyo-pneumothorax and subphrenic abscess are given in the section dealing with the former. The articles on Diseases of the Heart, by Dr. F. Forchheimer, and those on Diseases of the Blood and Ductless Glands, by Dr. Osler, need no commendation—they are what may be expected from such eminent authorities. Dr. James Tyson writes on Diseases of the Kidneys, whilst there is a full account of the general subject of Treatment of Nervous and Mental Diseases by Dr. Eskridge. In this and other articles on the nervous system we miss any extended notice of electro-therapeutics. The volume contains, further, a chapter on Mental Diseases and closes with sections on Diseases of the Skin and on Pregnancy and its Disorders, the respective writers of these articles being Dr. J. M. Chapin, Dr. H. W. Stelwagen, and Dr. T. Parvin. We have thus indicated some of the contents of this bulky volume, sufficiently, it may be hoped, to convey to our readers some idea of its scope and quality. It must not be supposed that the sections not mentioned here are less worthy of notice than those that have been cited, for, taken as a whole, the work is one which fairly reflects modern science and practice. It is, therefore, a book which may prove of service to the practitioner and it certainly has the merit of not being too much overladen with theoretical considerations.

Nouveaux Éléments d'Ophtalmologie. Par H. TRUC et E. VALUDE. En deux volumes. *(New Elements of Ophthalmology.* By H. TRUC and E. VALUDE. In two volumes.) Paris: A. Maloine, 21, Place de l'École de Médecine. 1896. Prix 20 francs. Tome i. pp. 604, Tome ii. pp. 713.

THIS work, though only professing to be an introduction to ophthalmology and intended for students, yet contains sketches and notices of many subjects that in more pretentious volumes are often passed over in silence. One of these, for example, is the history of ophthalmology, in which it is shown that considerable knowledge of the subject was possessed by the ancients. Herodotus, for example, mentions that Cyrus, King of the Persians, solicited the Egyptians to send him a celebrated oculist. Under the Ptolemies, the author tells us, the Alexandrian School was celebrated for its anatomical researches on the eye, though the burning of their magnificent library has prevented their works from descending to our time. The Greeks took up the subject, and some of the precepts as well as the practice of Hippocrates—as, for instance, the use of copper sulphate in conjunctival inflammation—still survive, whilst an altar was raised at Sparta to Minerva of the Eyes. No trace of eye-work can be found in Rome until the date of the Emperors, and the treatises of Celsus and Galen appeared. Soon after these writers the oculists' seals came into vogue, which were stones having one or more prescriptions engraved upon one face and the name of the surgeon on the other. After Paulus Ægineta darkness fell on science, and only in the sixteenth and seventeenth centuries were anatomical studies resumed under Vesalius, Fallopius, Ruysch, Briggs, Stenson, and others. The great French surgeon, Ambroise Paré, wrote a chapter on Wounds of the Eye in his work on surgery, and after him came Brisseau, St. Yves, Heister, and Winslow. All practised ophthalmic surgery. Many well-known names follow. Daviel, Petit, and Demours were celebrated as operators, whilst physiological optics were developed by Descartes, Newton, and Young. In later times it is only right to add, and it is freely admitted by the authors, that the Germans have taken a leading part in the development of scientific ophthalmology, as the names of von Graefe, Helmholtz, Donders, and Leber testify.

Again, there is a short but instructive chapter on the anthropological relations of the eye, dealing with the naso-ocular and orbito-occipital angles in different races, with the colour of the iris, the extent and direction of the palpebral fissure, the refraction, and other points. Short sections are also devoted to the comparative anatomy and to the development of the eye. The authors state very dogmatically that there are no dilator muscular fibres in the iris and maintain consequently that the movements of that membrane are simply those of constriction and relaxation; this theory involves the acceptance of two nerves, the third pair being the constrictors, and the sympathetic the dilator. In a section on the temperature of the eye the authors have brought together the scanty information that has been obtained, which is to the effect that in acute conjunctivitis the rise of temperature is 0·93° C.; in episcleritis, 0·49°; in keratitis with hypopyon, 1·45°; in lime burn, 1·29°; in iritis, 1·5°; in irido-choroiditis, 1·18°; and in dacryocystitis, 0·56°. In speaking of the mechanism of accommodation the authors approve of the explanation recently advanced by Tscherning, which is that in this act contraction of the ciliary muscle, tension of the zonule, and traction made upon the central part of the lens occur. Both the meridianal and the circular fibres of the ciliary muscle contract, the circular fibres recede slightly, press or drag backwards and outwards the zonule, and exert a traction in front on the lens. The radial or meridianal fibres advance slightly, stretch the choroid, and thus support the vitreous, which holds back the lens on which the forward traction of the zonule is being exerted. This theory certainly explains some points which are inexplicable upon the theory of Helmholtz. Thus, an increase in the curvature of the spherical lens of the fish is not conceivable as a result of the mere relaxation of the zonule. In both theories muscular action and the elasticity of the lens are brought into play. It is to be observed also that the ciliary muscle does not simply cause the anterior face of the lens to become more convex, but that, in addition, it draws the choroid forward, as Schäfer has remarked, and facilitates the forward expansion of the lens by opening the canal of Schlemm and permitting the escape of some of the aqueous humour.

The dioptrics of the eye and the various methods of instrumental examination are given in considerable detail. The reader will find an account of most of the apparatus that has been devised for the accurate determination of the functions

Hosted by Google

of the eye in regard to colour and refraction. A woodcut exhibiting phosphenes (after Serre d'Uzès) is given in which four crescents with their concavities inwards are depicted, but it seems to us that on pressure being made on the globe with the finger whilst the eye is rolled in the opposite direction as far as possible the demilunes have their convexity inwards. Under the head of Ophthalmoscope in the first volume the appearances presented by the fundus of the eye, with some account of their nature are given, which entails some repetition, both in regard to description and drawings in the second volume; no harm is done, but some space is lost. A good chapter is devoted to the preservation of specimens and to microscopic manipulation. The authors prefer Müller's fluid to alcohol and to corrosive sublimate, but formol is better than either, since it fixes well and does not stain like Müller's fluid. The osmic acid method is also mentioned, in which osmic acid is used in combination with chromic acid and glacial acetic acid. The formulæ for making gelatin-glycerine for preserving and exhibiting sections of the globes and those for staining the tissues of the eye are fully described. The second volume of MM. Truc and Valude's treatise is a clearly written manual. They consider that extraction of the lens in cataract, without iridectomy, is the operation that is now generally practised in France. They are of opinion that depression is a method of treating cataract that may again come into vogue, an opinion in which we entirely concur. In regard to the operative treatment of chronic glaucoma, they consider anterior sclerotomy to be the most appropriate. For the benefit of veterinary surgeons a chapter is devoted to the diseases of the eye in wild and domesticated animals. The work constitutes a very good *résumé* of the present state of the art and science of ophthalmology and is very carefully edited. We have noticed but few errors in the spelling of proper names, either German or English, though apart from the context we should hardly have known what to make of "shokes' Disk," intended for choked disk.

An American Text-book of the Diseases of Children, including Special Chapters on Essential Surgical Subjects; Diseases of the Eye, Ear, Nose, and Throat; Diseases of the Skin; and on the Diet, Hygiene, and General Management of Children. By American Teachers. Edited by LOUIS STARR, M.D., assisted by THOMPSON S. WESTCOTT, M.D. Pp. 1190. Philadelphia: W. B. Saunders; London: F. J. Rebman. 1894.

THERE is a growing tendency to issue medical text-books of large size written by numerous writers. This plan doubtless enables large books to be produced much more rapidly than when a single writer attempts to grapple with a large subject; and if writers of acknowledged authority are engaged on separate sections the plan is distinctly to be commended in representing the latest and most modern ideas of those best qualified to express their opinions. On the other hand, there are some inconveniences attached to this system of publication, the sections frequently overlap, and the methods of treatment and the weight of authority may vary materially in different parts of the work. The book before us appears to have received from the editor a large amount of care so as to eliminate the objections we have mentioned above, and he has gathered about him many writers from the most important medical centres of his country. In fact, he has endeavoured to stamp the work as national rather than purely local.

The introduction on the clinical investigation of disease and the general management of children is written by the editor, and in brief space he deals with several important subjects. Other sections, dealing with the diseases of the new-born infant, with the diathetic diseases, and with acute infectious diseases, follow. The paragraphs on diphtheria, tracheotomy, and intubation of the larynx are of considerable value from the lucidity of their explanations. The section on rickets is written by Dr. Lewis Smith and is rendered interesting by numerous figures and plates.

Where so many writers are concerned it is impossible to make separate mention of each, but reference may be made to the essentially practical character of the article on "Diseases of the Skin," which contains numerous prescriptions in addition to careful descriptions of the appearances.

The book is profusely illustrated with coloured plates, charts, and diagrams. It is to be regretted that the plates are of very unequal value and that in some cases they appear to have very little, if any, connexion with the text. It may further be pointed out that Plates XIX. and XX., although interesting in a work on general medicine, have little relevance to a book devoted to diseases of children. In some of the coloured plates, notably in those of Favus and Herpes Zoster, the colouring is so crude that the condition is almost unrecognisable. The figure on page 656 appears to have been wrongly named, the condition indicating opisthotonos rather than paraplegia.

LIBRARY TABLE.

Annales de l'Institut Pasteur. Edited by M. E. DUCLAUX. Tome X., No. 12. December, 1896. Paris: Masson and Co.—The articles in this periodical record of experimental investigation are of unusual interest: (1) Toxines non Microbiennes, by MM. Calmette and Delarde, dealing with the question of natural and acquired immunity; (2) Recherches sur le Pneumobacille de Friedländer, by M. Grimbert, chiefly dealing with its fermentative effects on various saccharine solutions; and (3) Contribution à l'Étude du Trypanosome des Mammifères, by M. Rouget, an extremely interesting account of a flagellated hæmatozoon which swarms in the blood of animals—horses, rats, donkeys, &c.—attacked with a peculiar disease. No cases in man have yet been recorded, but the disease appears to be prevalent among animals in Algiers and India. There is also an admirable critical editorial article on the Structure of Bacteria.

JOURNALS AND REVIEWS.

The Edinburgh Medical Journal.—With the new year this old-established journal commences a new series under the editorship of Dr. G. A. Gibson. It opens with an interesting retrospective paper by Dr. George Buchanan commencing thus: "Fifty years ago, on Tuesday, the 22nd December, 1846, I made myself insensible to pain by inhaling the vapour of sulphuric ether." He tells how he inhaled the vapour with a very simple apparatus and how his father, to prove that he was not shamming, pushed a lancet under one of his finger nails, which was naturally accepted as a thorough proof of his insensibility, seeing that the "patient knew nothing of the action." Dr. W. R. Gowers reports a case of Paralysis of the Fifth Nerve, "singularly complete and almost isolated." Dr. Lauder Brunton publishes the first instalment of a lecture on Pericarditis, written in his usual clear and incisive style; and Dr. Robert Fleming has a paper on Ascending Degeneration in Mixed Nerves, with Experimental Results. Altogether the new series promises well.

The Dublin Journal of Medical Science.—Mr. R. Glasgow Patteson reports a case of Successful Disarticulation at the Hip-joint. The chief points observed were the prevention of hæmorrhage by an elastic tourniquet and an incision planned so as to divide the femoral vessels last. Dr. A. Birmingham has a note on Asymmetry of the Sternum. Fifty-four sterna were examined, of which twenty-seven showed a diminution of the vertical depth of the manubrium on the right side and twenty on the left, while seven were symmetrical.

Hosted by Google

The Journal of Anatomy and Physiology. Conducted by Sir W. TURNER and Professor M'KENDRICK. Vol. XXXI., Part 2. January, 1897. London: Charles Griffin. Price 6s.—This part contains several interesting articles. 1. Alfred H. Young, M.B. Edin.: Abnormalities of the Middle Sacra Artery and their Morphological Significance. 2. Swale Vincent, M.B. Lond., and H. Spencer Harrison, Student, Royal College of Science, London: On the Hæmolymph Glands of some Vertebrates. This paper includes an account of the glands in question in fifteen species of mammals, six of birds, two of reptiles, and in several fishes. 3. Gordon Sharp, M.D. Edin.: On the Action of the Products of the Organism of Diphtheria on the Heart Muscle of the Frog. He finds that diphtheria poison is to be classed with the acids which have as their final action the stoppage of the heart muscle in diastole. Hence he believes that the general line of treatment in diphtheria is stimulation without ultimate depression. 4. Albert A. Gray, M.D.Glasg.: An Investigation into some of the Principles of Auscultation — an article containing the results of many careful experiments and observations deserving the study of physicians. 5. R. J. Lloyd, D. Lit.: The Genesis of Vowels, with a plate. 6. On the Interpretation of the Phonograms of Vowels, by the same author. 7. Herbert Page, M.D.: Post Mortem Artificially Contracted Indian Heads. These are made by the Indian tribes of South America, who preserve them as trophies or idols. About twenty-seven specimens are known to exist, and Dr. Page gives some curious drawings and details respecting them. 8. Leslie Buchanan, M.B. Glasg.: The Glands of the Ciliary Body, with a plate. 9. Joseph Griffiths, M.D. Edin.: A Descriptive Account of the Genital Apparatus in the Boar and in the Pig. 10. R. Broom, M.D. Glasg.: On the Occurrence of an Apparently Distinct Prevomer in Gomphognathus; and by the same author — 11. On an Apparently hitherto Undescribed Nasal-floor Bone in the Hairy Armadillo. 12. T. Wardrop Griffith, M.D.Aberd., Professor of Anatomy, Yorkshire College, Leeds: On an Abnormal Muscle of the Hand, with Remarks on the Course of the Radial Artery. This article relates to the first dorsal interosseous muscle. 13. A. F. Tredgold, London Hospital: Variations of Ribs in the Primates, with especial Reference to the Number of Sternal Ribs in Man. 368 specimens of different animals were examined to enable the author to draw his conclusions. 14. John G. M'Kendrick, M.D.Aberd.: Notes on certain Physical and Physiological Measurements and Estimates. A very useful series of data, to be classed with Vierordt's "Daten und Tabellen." 15. Thomas H. Bryce, M.B. Edin.: Note on Two Useful Accessories in Serial Section-Cutting by the Paraffin Method. 16. David Harris, M.B.Glasg.: Summary of a paper entitled "On the Variations in the Character of the Contractions of Striated Muscle with Periodic Stimulation of some Duration and on Recovery of the Muscle," by Alex. Rollett of Graz. Lastly, the proceedings of the Anatomical Society of Great Britain.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—The fourth meeting of the session was held on Jan. 13th in the Medical Library of University College, Dr. Aust Lawrence being in the chair.—Dr. Waldo showed a patient with Thoracic Aneurysm, in whom tracheal tugging was well illustrated.—Dr. J. G. Swayne and Mr. W. J. Penny made remarks on the case.—Dr. T. Fisher showed a number of Mounted Pathological Specimens recently added to the Royal Infirmary Museum.—Dr. W. H. Newnham read a paper on Three Vaginal Hysterectomies for Malignant Disease.—Dr. W. C. Swayne, Dr. J. G. Swayne, Dr. Michell Clarke, Mr. Greig Smith, Mr. Morton, Mr. Ewens, and Dr. Aust Lawrence spoke at length on the paper.—Dr. B. Rogers read a paper on a Case of Mediastinal Inflammation.—Dr. Michell Clarke, Dr. Fisher, and Dr. Waldo remarked on the paper.

New Inventions.

(1) A NEW HÆMOGLOBINOMETER AND (2) A NEW HÆMOCYTOMETER.

THE principle of the hæmoglobinometer invented by Dr. George Oliver, and described by him in the last Croonian Lectures, is that of the tintometer—viz., the measurement of colour by means of graded glass standards. Doubly transmitted light is used, the blood being diluted to fill a cell having sulphate of lime at the bottom (under a cover-glass) so as to form a dead-white reflecting background. The glass standards, which match the colour of blood to a nicety, are mounted on a similar white background for comparison. It will be noticed on careful inspection that besides the successive additions of colour in going from one glass standard to the next there is a difference of tint as well. In working out the standards it was found that, although a particular liquid, such as carmine, could be made up to match blood at a particular point of the scale, yet on dilution there was considerable divergence. The reason for this is that every liquid has on dilution or concentration a specific colour curve, which is a characteristic of the substance as its specific heat. Consequently it is impossible to read accurately the variations in depth of colour of one substance by means of a scale composed of a single other substance. This important physical law seems to us to put Von Fleischl's hæmometer, in which a wedge of unicoloured glass is used as the standard, out of court altogether. In Dr. Oliver's hæmoglobinometer each degree of the standard is graduated separately by means of the tintometer against the previously ascertained colour curve of diluted blood. To render the colour easier to read the brilliancy of the diluted blood against the white background is lowered by covering the cell with a pale blue tintometer glass. There are twelve graduations in the standard, ranging from 10 to 120, intermediate points being read by means of tinted glass riders, of which two are sufficient for clinical work, but nine are supplied for physiological investigations. Normal blood reads 100 on the scale, corresponding to 1·5 per cent. of hæmoglobin. Although a daylight set is made, the candle-light set of standards is recommended as being more delicate. The comparisons between the blood and the standards are made through a camera tube so as to exclude all extraneous light. Either a collapsible tube contained in the case holding the apparatus may be used or a sliding tube on a stand, the latter being much more convenient.

When a glass tube is drawn out longitudinal lines or minute ridges are formed in the glass. If the tube be filled with a transparent liquid and a distant light, such as a candle flame, be viewed through it, a tiny image of the flame is formed by each ridge, the whole series appearing as a bright transverse line. This fact is made use of in the hæmocytometer invented by Dr. Oliver. Ten cubic millimetres of blood are washed into a flat graduated tube and diluted with Hayem's solution until the line of light formed by the images of a candle flame about ten feet off is just visible. The level of the liquid in the tube is read off and the graduation corresponds to a definite proportion of corpuscles present in the blood. With a little practice very delicate readings can be obtained. The instrument is intended to be used in conjunction with the hæmoglobinometer noticed above. By combining the results the exact condition of the corpuscles themselves can be ascertained. This is important, as it is possible for the corpuscles to vary considerably in the amount of hæmoglobin they contain, although the state of the blood, taken from a general point of view, might appear normal.

These instruments appear to be the most accurate and by far the most delicate yet designed for the measurement of blood. Both are made by the Tintometer Company, Limited, 6, Farringdon-avenue, E.C., who on application will gladly send a representative to demonstrate their use and working.

THE LANCET.

LONDON: SATURDAY, JANUARY 23, 1897.

WE cannot wonder that the calamitous news about the plague-stricken condition of Bombay and Karachi claimed a separate paragraph in the QUEEN'S Speech. The epidemic, we are assured, shows no signs of decrease, notwithstanding the precautions adopted by the local authorities; and we can only trust that the stringent measures which the Government have been directed to take for the eradication of the pestilence may prove more effectual. It would, indeed, be difficult to imagine a more lamentable state of affairs than the large, important, and hitherto prosperous city of Bombay presents at this time. The situation has been rapidly growing from bad to worse, and the exodus still continues, according to the latest accounts. We have had graphic and gruesome pictures of the sickness, mourning, and desolation which prevail at Bombay, of the deserted streets, closed shops, unfrequented law-courts, and general paralysis of business, of the wholesale departure of the people, of the difficulty of disposing of the dead, and of the terror of the native medical men, who refuse to visit or touch the sick lest they contract the disease. Europe and the outside world have naturally taken alarm and have almost universally adopted quarantine arrangements against Bombay.

Happily for us we have had in this country no experience of this scourge since the great plague followed by the fire of London, and our knowledge of it is mainly traditional and derived from literature and historical romances. There have, of course, been several descriptions of the outbreaks of Levantine plague, which have now and again occurred in more modern times in the East. The late Mr. NETTEN RADCLIFFE some years ago prepared a summary account of the then existing information, but, speaking generally, people did not occupy themselves with what appeared to be a remote contingency as far as they or their country were concerned. The late epidemic at Hong-Kong and in China aroused, of course, a certain amount of public attention and added to our knowledge of bubonic plague in that a specific micro-organism was discovered in the subjects of that disease. Still, European pathologists have really had but little opportunity of investigating plague by the more modern methods of scientific research. The news, if found to be true, that the lower animals—rats, pigs, and domestic fowls—are affected by the disease, and that ants preying upon the dead bodies of the plague-stricken smaller animals may be the disseminators of a pathogenetic microbe, opens out a new and wide field for investigation. As regards the causes—the foster-mothers and nurses of the disease—which led up to the present epidemic in Bombay, it may, we think, be rightly inferred that these were attributable to a long course of neglect of sanitary precautions. The descriptions given of the state of some of the districts and native quarters of Bombay show that a muck-heap or hot-bed was being slowly but surely prepared for the germs of this and other epidemic diseases when once introduced from without. That there have been opportunities of late years for the introduction of the germs of bubonic plague into the city cannot be denied, notwithstanding that we may fail to trace exactly the "how" and the "when."

What should now be the principles—the common-sense line of action—that should be followed in respect of the plague in India—at Bombay, Karachi, Poona, and whithersoever the disease has been carried and has manifested itself? In the first place it should be a subject for anxious consideration whether, under the circumstances and in view of our international obligations, steps should not be at once taken either to prohibit the pilgrimage to Mecca altogether or, at any rate, to discourage in every way in our power pilgrims from India from undertaking that religious but perilous journey. The great flight from Bombay having already taken place, it is obviously too late to do anything in this respect as far as the rest of India itself is concerned. We must be guided generally in our course of action in this as in the case of other known infectious diseases. What is wanted in Bombay and Calcutta is the purification, as far as practicable, of the foul native quarters of these Eastern cities, and, to be thoroughly logical, their destruction by fire even should be considered. There should be large open spaces provided somehow in the place of the overcrowded foul buildings. Large camps on open, healthy sites might be supplied for temporary occupation so long as the epidemic lasted. Segregation hospitals for the plague-stricken and infected people are required; also, an organisation for a systematic house-to-house visitation, public kitchens or depôts for the supply of food for the famine-stricken natives, and numerous small dispensaries for the supply of medical aid in connexion with a system of ambulance transport might be instituted. There should be available, also, means of ready disinfection by heat or otherwise, and for the burning of infected and fouled clothing at several convenient centres. A central public health committee, composed of some practical sanitary engineers and medical officers, with one or two good organisers and energetic administrators, and a large staff of executive subordinates, should be, and probably has already been, formed with power to devise and carry out what is held to be necessary. We would also counsel that application should be made to Hong-Kong for the temporary services of some medical official of practical experience who is thoroughly acquainted with all that had been done there during the late outbreak of plague. We sketch in outline the principles which should be followed in attempting to arrest or limit the progress of the epidemic. It must be left, however, to the local authorities acquainted with native customs to determine what is possible or practicable.

THE valedictory address on the subject of Antiseptic Midwifery (which is published in full at p. 221) delivered by Dr. CLEMENT GODSON on the occasion of his retirement from the presidentship of the Gynæcological Society should be read by all practitioners of obstetrics,

Hosted by Google

whether engaged in hospital or in private practice. The subject is a momentousone, touching the safety of puerperal women, of whom four or five thousand still die annually. Dr. GODSON, in his address, does not pretend to announce anything startlingly new or original. His exposition of the efficacy of antiseptics, and especially of corrosive sublimate, has been anticipated by Sir JOHN WILLIAMS, Dr. BOXALL, Dr. CULLINGWORTH, Sir WILLIAM PRIESTLEY, and many others. But, for all that, it is so clear, so simple, and so practical, it is based on so striking an experience, and is, withal, so just to other obstetric authorities, as to entitle him to the gratitude of the Society and of the profession. The case of the lying-in woman is very familiar, daily in its occurrence, and apt to be regarded as a purely natural or physiological process. Practitioners are thus thrown off their guard in respect of its risks. But the fact remains that somehow or other four or five thousand women each year come by this process to their death, and there is every reason to think that such a mortality of the puerperal cases of the country might be reduced certainly to one-half and probably to a much lower proportion.

Half the interest of Dr. GODSON'S address is in the vividness with which he illustrates the mortality of the lying-in hospitals under the old *régime* and prior to the introduction of the use of antiseptics. He speaks particularly with reference to the case of the City of London Lying-in Hospital, which is now 124 years old. The account he gives of the constant and quickly-recurring outbreaks of puerperal septicæmia leading to such a number as necessitated the closure of the hospital for weeks or months makes us almost wonder how it was possible to get physicians to serve on the staff. His connexion with the hospital goes back twenty-seven years. At that time (1870) the patients were dying at the rate of one in nineteen, so that he soon had to appeal, in conjunction with Dr. GREENHALGH, to have the hospital closed. All that fresh paint and colouring could do, with new palliasses and hair mattresses in place of old feather beds, and repaired and double-trapped drains, was done, and it must be admitted with obvious reduction of mortality, lasting for a time. Then followed a gradual rise till another appeal (1877) was again necessitated, and Dr. DE CHAUMONT of Netley was invited to report on the hospital. Great alterations were made at an outlay of £4500, and the hospital was closed for sixteen months. In the immediately ensuing eight months of 1879 the mortality was reduced to 1 death in 278 cases. But with 1880 came the crushing disappointment of a mortality of death 1 in 19. More money was spent on the hospital and a sub-committee recommended that the hospital should be pulled down and rebuilt. Only the back part of the building was pulled down, alterations were made costing £1000, and the hospital was again closed for five months. In five more months it had again to be closed for cleansing, disinfecting, and whitewashing purposes, with marked *temporary* improvement in results—1 death in 104 cases.

The mortality again began to rise and the closure had to be resorted to in 1886 for a mortality of 1 in 44. But now a new state of matters was to be introduced fraught with new hope for lying-in women and a new lease for lying-in hospitals which were rapidly becoming discredited. An agent that hitherto had been regarded chiefly as a poison came to be known as more potent in the saving of lying-in women—at least, in lying-in hospitals—than all the costly repairs and closures that had chequered the history of the hospital in its past years. The physicians of the General Lying-in Hospital—Dr. (now Sir JOHN) WILLIAMS and Dr. CHAMPNEYS—published in 1884 the admirable results of their use of corrosive sublimate as an antiseptic. It was adopted by Dr. GODSON and his colleagues in the City of London Lying-in Hospital, and in the way he describes in a footnote to his address, with the result that from July 1st, 1886, to Sept. 30th, 1887, no fewer than 480 confinements took place without any death. In the last ten and a half years 4608 women have been delivered with 11 deaths, or 1 in 419. From Jan. 1st, 1892, to Dec. 31st, 1896 (five years), there were 2892 deliveries with 3 deaths, and these, not from sepsis, but 1 from embolism and 2 from puerperal eclampsia. The change is momentous, and, as narrated by Dr. GODSON, most impressive. He was induced to make the statement on which we are commenting chiefly by a remark made by one of his predecessors in the Presidentship of the Gynæcological Society—Dr. BANTOCK—who attributed "the marvellous effects of the antiseptic method in midwifery practice to the principle of cleanliness, and called attention to the large number of deaths due to poisoning by corrosive sublimate." Dr. GODSON assures us that in the City of London Lying-in Hospital not the slightest sign of mercurial poisoning has been observed, and does not see why the system should not be used in private practice also. There is probably not the same risk to the lying-in woman in a private house. But private houses have their own special risks. And it is clear that in private midwifery practice there are frequent cases of puerperal pyrexia, often fatal, which are now rarely seen in well-regulated lying-in hospitals. It is a question for every individual practitioner to consider for himself. Until of late years the results of private obstetric practice would bear a favourable comparison with those of lying-in hospitals. Now it is rather the other way. And it is for private practitioners to maintain their former advantage. Dr. GODSON describes with creditable candour and force the distress he felt in losing his first private patient from puerperal septicæmia. In no part of his address is he more true to the general feeling of the profession than here. He now evidently considers such an experience almost impossible, apart from some internal and accidental source of mischief, as latent pyo-salpinx. Let every practitioner be as fully and justly persuaded that his methods are safe. He will then equally advance the security of his puerperal patients and his own professional happiness.

WHEN the regulations for the conduct of the half-yearly meetings of Fellows of the College were framed we pointed out that inconvenience would be experienced from fixing the quorum at so high a number as thirty, the same number as for the larger general meetings of Fellows and Members. Our objections have been justified by the proceedings at the half-yearly meeting of Fellows held on Jan. 7th.[1] It looked

[1] THE LANCET, Jan. 16th, 1897, p. 199.

Hosted by Google

at first as if the quorum would not be obtained, but at the end of a quarter of an hour a small balance over the quorum had been secured, and the meeting was then composed of thirteen members of the Council and twenty-six other Fellows. The quorum, however, could not be maintained till the close of the proceedings.

The *pièce de résistance* of the agenda consisted of two motions by Mr. HOLMES and by Mr. RIVINGTON respectively regarding the case of Mr. R. B. ANDERSON, with which everybody sympathises, even when fatigued by frequent repetition. In Tobago and Trinidad Mr. ANDERSON was the victim of judicial harshness and persecution and denied the right to dispose of his professional services by retiring from a case when circumstances rendered it expedient and possible without injury to his patient to do so. He was also precluded from recovering his reasonable fees for attendance. For the exercise of his professional rights mainly derived from his diplomas from the College he was fined and deprived of his fees, whilst to crush his resistance to illegal proceedings he was subjected to two actions for contempt of court which he successfully surmounted, had exorbitant bail imposed upon him, and not being able immediately to produce it was committed to prison. The verdict of £500 damages he obtained in the action which he brought in the Queen's Bench against the colonial judges has been of no service to him, and he finds himself additionally weighed down by the costs of the action still due to his solicitor and to one of the judges who was acquitted of malicious action. At meetings held in the College, both by the Fellows of the College and by the Fellows and Members together, resolutions have been passed bespeaking the action of the Council in his favour. In July the Fellows of the College requested the Council to instruct the representative on the General Medical Council to forward in every way that seemed feasible the objects of the Civil Rights Defence Committee in the case of Mr. ANDERSON. The Council adopted the identical terms of the resolution, and Mr. BRYANT, the representative of the College, undertook to do what he could. But the net result of his speech, as Mr. HOLMES has pointed out, was that "Mr. ANDERSON would find additional difficulty in obtaining the justice to which he is entitled." It was not, therefore, surprising that Mr. HOLMES, who has displayed a warm interest in Mr. ANDERSON'S case, should have moved to ask the Council whether their representative had correctly interpreted his instructions. The motion was, however, lost by a single vote.

The Fellows and Members of the College last November carried a resolution asking the Council to contribute "a substantial sum towards the defence of the rights of Mr. R. B. ANDERSON, these being the common rights of the Fellows and Members which the College under By-law XV. has undertaken to defend." The Council replied, re-affirming the resolution adopted in August last—"That the Council, while sympathising with Mr. ANDERSON in the circumstances in which he is placed, do not feel justified in devoting any of the funds of the College towards the promotion of his appeal to the House of Lords." This resolution of the Council was evidently no sufficient answer to a general resolution asking for the "contribution of a substantial sum towards the defence of the rights of Mr. R. B. ANDERSON." It is to be observed that the appeal to the House of Lords, though very important for obtaining a declaration of the law and pecuniary compensation for Mr. ANDERSON, is not, like the appeal to the Privy Council, a direct method of restoring to him his former position at Tobago and his right to practise there. To this effective means of securing the redress of Mr. ANDERSON'S disabilities—means stamped with the approval of the Council of the College in June, 1894—Mr. RIVINGTON'S motion was, we presume, intended to draw attention. Without committing itself to any declaration upon the exact scope of By-law XV. or any indication of being prepared to afford pecuniary aid the Council did at that time decide to afford to Mr. ANDERSON, at the very least, the moral support involved in the appointment of two representatives on the Civil Rights Defence Committee to further the appeal to the Privy Council, the only appeal which the committee had then undertaken. If the by-law only carried with it the obligation to afford to Fellows and Members disturbed in their "rights, privileges, exemptions, and immunities" the moral support of the Council there can be little doubt that the applicability of the by-law to Mr. ANDERSON'S case would not only not have been questioned but cheerfully accepted. It is perfectly right for the Council to exercise a jealous vigilance over the expenditure and to be very careful not hastily to commit itself to pecuniary obligations for the protection and defence of the Fellows and Members. At the same time the Council is bound to fulfil its obligations under the by-law even if they do involve a considerable expenditure, and the position of the Council at present is very peculiar and embarrassing. The great majority of the members of the Council, we believe, will not admit any pecuniary obligation under the by-law, and at the same time refuse to submit the by-law with the particulars of Mr. ANDERSON'S case for the opinion of counsel. They will probably not retire from this position unless, and until, Mr. ANDERSON makes formal application to the Council to protect him in the exercise of the rights, privileges, and immunities guaranteed to him under By-law XV. of the College.

IT has been announced in the public press that, on the invitation of the Austrian and Russian Governments, an International Conference will be held as to the prevention and control of bubonic plague should that disease advance towards the confines of Europe, and that Her Majesty's Government have consented to be represented at it. It is further stated that the Conference is likely as assemble in Vienna. We believe the announcement to be in several respects premature, but there is no question but that various Powers—notably, those bordering on the Mediterranean—have practically decided to take some common action in the matter. The attitude of this country becomes, therefore, a matter of primary importance. Hitherto we, as a nation, have based the whole of our public health action and administration on the sound principle that individuals are to be treated as healthy unless they are honestly believed to be sick. We thus maintain, for purposes of public health,

Hosted by Google

the sacred traditions handed down to us by our forefathers in the matter of the criminal law—namely, to hold all innocent who are not proved to be guilty. This tradition, in its application to public health, is now at least half a century old, and it has been an inestimable boon in the promotion of public health and in the saving of life. So, also, other nations have advanced in public health just to the extent to which they have acted on the same principle. It was largely the unfortunate abandonment of this principle, which had been internationally proclaimed at the Venice Conference, that led to the breakdown of the Paris Conference as regards action in the Persian Gulf; and it must be a satisfaction to know that that principle, to which Great Britain has consistently adhered, is already definitely established by this country in connexion with her intended dealings with plague. When the last remnant of our quarantine law was abolished last session, the Government, doubtless acting on the advice of the medical officer of the Local Government Board, declared by an official Order that they would deal with plague on the same lines as they had dealt with cholera. This Order is practically the law of the land on the subject; and whatever other nations may do in their ports we trust that the British Government will not, as regards English ports, recede from an attitude which has more than any other tended to raise the standard of health and to save thousands of lives from preventable disease. Unfortunately, we are handicapped. Some of the most retrograde Governments of the world have their sway in the basin of the Mediterranean, and they can now point to the action by which Malta has opened the year of grace 1897 by actually setting the ball rolling with "twenty days' quarantine" on all arrivals from India, even when the highest standard of health has been maintained during the whole voyage. It is this reversion to the days of mediæval sanitary neglect and ignorance of the true laws of health that defeats more than anything else international coöperation and unanimity with regard to action on the only sound laws of health.

"Ne quid nimis."

A CENTRAL HOSPITAL BOARD FOR LONDON.

WE are pleased to see in almost every quarter indications of a serious determination to investigate the faults of our voluntary hospital system, with a view to its perpetuation and improvement. We have no wish to see so fine a feature of English humanity and charity disappear or to have the system exchanged for State- or rate-supported institutions. It is for this reason that we have ourselves initiated a searching inquiry into the working of our voluntary hospital system. For the same reason we welcome every movement conceived in a friendly spirit and having for its object the improvement of the administration of our hospitals. One of these movements aims at the formation of a Central Hospital Board for London, as recommended, it will be remembered, by the House of Lords Committee on Hospitals which reported in 1892. A meeting to further this project is to be held on Monday next, at 4.30 P.M., at the Royal United Service Institution, Whitehall, when Sir William Broadbent, Dr. Lauder Brunton, Mr. G. D. Pollock, Mr. Victor Horsley, and others are expected to speak. The general nature of the scheme is before us, with a list of medical and other gentlemen who favour it, and a preliminary list of a general committee for stimulating public feeling in its support. It must be admitted that this scheme has not been enthusiastically received. Probably this has been due to the nature of the case rather than because of any dissent from the general principle of the scheme. The hospitals are separate units and their disposition is to remain so. They have to fight for their existence and they are apt to think they can best do so by preserving absolute individual freedom. But the result of this utter want of coöperation has been to reduce the hospitals themselves to a state of uncertainty and impecuniosity; to make public opinion critical rather than charitable; and to bring about a rapidly changing sentiment in the medical profession towards institutions to which it has hitherto looked with respect and gratitude. With regard to the meeting to be held on Monday we need not now do more than say that we feel a deep interest in the scheme. We are not blind to the difficulties of carrying it into execution and of creating a central body that shall supervise and inspect our hospitals and dispensaries. But it will do so in no compulsory way and as much in their interest as in that of the public and of the medical profession. We have always hoped that the Council of the Hospital Sunday Fund (with the assistance of that of the Hospital Saturday Fund) might have fulfilled the functions of such a board. It has given much to the hospitals and has had to express strong opinions on evils and defects in the system, and its final word has not been spoken with respect to the monstrous abuse of the out-patient system. It seems almost inevitable therefore, that a body must be created for the purpose of friendly investigation and, where necessary, of correction. One most pleasing feature in the preliminary list of the general committee is the inclusion of members—and much respected members—of the staffs of important hospitals in London, as well as of many influential laymen. We can imagine nothing better for our voluntary hospital system than the appointment of a strong central board, representative of all who support hospitals as well as of the medical profession. The staffs of our hospitals have the responsibility of contributing the indispensable element of all hospital charity and owe it to the public and to their own profession to do so on well-defined and approved conditions.

THE MIDWIFE AS OPERATOR.

"A LITTLE knowledge is a dangerous thing"—unless its possessor knows how little it is. Midwives are, without doubt, of great value to a community when it is fully recognised that they are specially trained nurses and nothing more. The moment a midwife steps beyond the narrow limits of her legitimate sphere of action she becomes a veritable danger. It is quite unnecessary to lay any stress on the point that midwives should not attempt anything that could be called operative midwifery. That is acknowledged by everyone; but it is by no means needless to utter a warning against a tendency which undoubtedly exists for them to take upon themselves the performance of some of the minor operations of surgery. Even the smallest surgical operation is full of risks and requires an amount of technical knowledge which is not possessed by a midwife; and the complications which may occur and the sequelæ which may follow need all the care of a skilled surgeon for their recognition and treatment. Among the many dangers which beset even the most trivial operation may be mentioned especially hæmorrhage and sepsis. Without a knowledge of the course of the arteries it is not in the power of an operator to avoid occasionally

Hosted by Google

wounding important vessels and fatal hæmorrhage may occur; and should it chance that hæmophilia is present the danger is increased a hundredfold. From sepsis also the risk is great, for though a midwife may talk learnedly of germs and antiseptics, yet her practice of asepsis is usually very faulty. Should septic complications arise they are often unrecognised until the case is hopeless. A very good example of the harmful effects which may follow even a very simple operation by a midwife is reported in another column. The wife of a labourer was attended in her confinement by a midwife employed by a lying-in charity; on the following day the midwife noticed that the child was tongue-tied, and she divided the frænum linguæ with a pair of scissors. It is said that no hæmorrhage occurred at the time, but the next day blood flowed at intervals from the mouth. At first the midwife contented herself with washing out the child's mouth with a little water, but ultimately, after the hæmorrhage had lasted for twenty-four hours, a medical man was called in, and as the bleeding recurred the child was admitted into the Norfolk and Norwich Hospital, where he died a few hours later. The stomach and intestines contained much blood. The wound is described as having been from half to three-quarters of an inch in length. The midwife urged in excuse that she had done the operation successfully on several other occasions, and the jury at the inquest returned a verdict of "Death from misadventure." Unfortunately, this case does not stand alone, and it would be well if measures could be taken to do away with such unskilled operating.

THE COMMERCIAL VALUE OF A MEDICAL PRACTICE IN FRANCE.

IT has recently been decided by a Parisian tribunal that a medical practice in France possesses no commercial value whatever. We are indebted to *La Presse Médicale* for the following particulars of the case which led to this important decision. In 1885 an unqualified individual named Alliot opened an institution in Paris where he professed to cure cancers of the breast by a secret method of treatment which had been handed down to him from an ancestor of his who was physician to Louis XIV. The business apparently flourished until 1893, when Alliot died; whereupon his widow came to terms with her brother-in-law, Florent Alliot, who agreed to exploit his deceased brother's practice for her benefit. The new cancer curer was an *officier de santé*, and up to January, 1896, all seems to have gone on as well as possible. For one reason or another discord then arose between the pair, and having ceased his attendance at the institution Florent Alliot set up on his own account in another street. The widow, however, being a woman of resource was not easily discouraged. Amongst her acquaintances there happened to be a universal genius named Bernard, with whom she incontinently entered into partnership, and the original cancer-curing concern was soon going on as merrily as ever. Upon this Florent brought an action against the new associates, alleging that his late brother's practice was his exclusive property, and claiming damages to the extent of 4000 francs. The widow and Bernard, in reply to this attack, immediately lodged a counter-claim for 5000 francs damages against the plaintiff, whom they further accused of fraudulently copying the prospectus of their old-established institute and also of appropriating to himself the stock cures belonging thereto. So far the details are sufficiently mean and sordid, but the judicial ruling, being equally applicable to properly qualified practitioners, is worthy of note. A medical practice, said the presiding magistrate, cannot be made the basis of a contract, inasmuch as it reposes exclusively upon the confidence which the medical practitioner's knowledge and experience have inspired. That confidence is not transferable as a gift, still less, being essentially non-commercial, can it be sold. When a medical man dies his practice dies with him; in the eye of the law it has ceased to exist and cannot, therefore, be exploited by the heirs, even though these should associate with themselves a qualified person. The several parties in the present case are consequently nonsuited.

THE ORGANISATION OF PROVIDENT DISPENSARIES BY THE PROFESSION.

A CORRESPONDENT, "Beta," writes on the subject of the organisation of provident dispensaries by the profession as a piece of tactics in the "Battle of the Clubs" and on the supposition of an undisguised antagonism on the part of the old friendly societies towards the profession. In order to checkmate these societies he argues that it would be necessary for the profession, either alone or with the help of insurance companies, to cater, not only for the delicate part of the working-class population, which is the part that supports the medical officer in this controversy, but for the strong young men who need the medical officer but little, but want the benefits of a sick club of assured soundness that will last their lives and yield them 10*s.* or 12*s.* a week in sickness. Moreover, there must be such an organisation of these throughout the country that men migrating from one place to another will be able to carry with them the advantages of their membership. There is much material for consideration in our correspondent's letter. But we would point out that he is proposing a very large undertaking to the profession, which would immensely complicate its anxieties and distract its attention from proper medical work. Coöperation with insurance offices in its present form is liable to the most serious objections of small pay, canvassing, and subjection to commercial companies. Recognition of the provident principle in some form is essential and has been the practice of the profession for generations. But the more the profession keeps clear of commercial companies and associations the better; it should confine itself to strictly medical work on terms honourable to the medical man and considerate to the working-classes.

THE ELECTION OF CORONER FOR THE LOWER DIVISION OF PEMBROKESHIRE.

ALLUSION was made in THE LANCET of Nov. 21st, 1896, page 1477, to the fact that a vacancy had occurred in the office of coroner for the Lower Division of Pembrokeshire, and that the candidates comprised one medical and five legal candidates. The election is fixed for Feb. 2nd, and the issue, we are informed, practically rests between two candidates—Mr. Herbert Price, solicitor, and Mr. Hugh Pughe Jones Price, surgeon. The first-named gentleman bases his claim for the office upon the circumstance that he is the son of the late coroner and is at present acting as deputy coroner. He is about twenty-five years of age and at the present time holds various appointments, the value of which amounts to between £400 and £500 per annum. Now we would strongly urge the county councillors with whom the election rests to make the appointment without fear, favour, or affection. Politics and private friendship ought not to be allowed any weight in the election of such an important office as that of coroner. What are the claims of Mr. H. P. J. Price, the medical candidate? He obtained the qualifications M.R.C.S. Eng. and L.S.A. in 1872, and must therefore be at least forty-five or nearly double the age of his legal opponent, while still being in the prime of life. He is consulting surgeon to the Haverfordwest Infirmary and has held for some time the offices of medical officer, medical officer of health, and public vaccinator of one of the districts of the Narberth Union. He has also been certifying factory surgeon. The vacant district is an agricultural one, but contains the towns

Hosted by Google

of Haverfordwest, Tenby, Pembroke, and Milford. It extends thirty miles in one direction and twelve in another. The population is 53,925 and the inquests average about eighty yearly. Mr. H. P. J. Price is the only medical candidate, and though other lawyers are in the field the issue will, it is said, be between the two—Mr. Herbert Price, solicitor, and Mr. Price, surgeon. There ought to be no difficulty in deciding. From what we have already stated the medical candidate is the older and more experienced man. But the county councillors must also bear in mind that the duty of a coroner is not only to hold an inquest as to the cause of death, which of itself is distinctly and essentially a medical function: it rests with him entirely to decide whether a death is natural or unnatural, whether the cause of a sudden death is or is not unknown, and whether a death has or has not been a violent one. These questions can only be answered satisfactorily by an experienced medical practitioner—a most important point. For useless inquests are not only a grievous infliction upon those who have to act as jurors, but they cause much unnecessary pain to the bereaved relatives. The viewing of a body by a legal coroner is an absolute farce; to the medical coroner it is an object lesson which he has studied since his early student days. Then as to the taking of evidence, about which so much capital has been made for legal coroners, there is some misapprehension. A surgeon who has discharged the duties of the appointments held by Mr. H. P. J. Price for years past has had more experience of the sifting of evidence such as is required by a coroner than the most experienced solicitor. The inquisition *super visum corporis* is distinctly a medical inquiry and it is greatly to be hoped that the next amendment of the Coroners Act will be one making a medical qualification essential to the office of coroner. Meanwhile, city and county councillors will do well to elect experienced medical candidates who alone can deal satisfactorily with the important questions submitted to them both before, and during, an inquest.

HAS THE FISH A MEMORY?

PROFESSOR LUDWIG EDINGER is collecting information on this point and writes to us as follows:—"Have fish a memory? A request for information. There is a general opinion that fish have some sort of memory, that they can recognise people, know how to find or to avoid places where they have made formerly some experiences, that fish which have once escaped the rod know the bait, &c. It is highly desirable that all experience of this kind should be collected in the interest of comparative psychology. The reason is that till now we believed the function of memory to depend on the action of the brain cortex. All experience in man and in the higher animals has led to that conclusion. During the last years it has been proved that fish have no brain cortex at all. They are the only existing vertebrates without a brain cortex. Now if we could prove beyond the possibility of doubt that fish really have a memory, that they gain experience and can make use of it, then we shall have to give up the till now general opinion that memory has its seat in the brain cortex. Therefore it is extremely important to have an entirely new set of experiences." Professor Edinger then asks all anglers and naturalists to communicate to him any experiences they may have had, requesting them particularly to take nothing for granted, as the smallest observation may prove of the greatest importance. Professor Edinger's address is 20, Gartnerweg, Frankfurt, Main. Here, then, is a splendid chance for anglers to tell their pet tales and to throw light on this interesting question. Many incidents which commonly occur to anglers would decidedly o against the theory that fish have memories. Thus, a fish which has had a fly broken in his mouth will often immediately take another, and on being captured the broken one may be found still sticking in his mouth, and then it is well known to fishermen that a pike which escapes while it is being played will often again ferociously seize the bait if it be at once temptingly offered him. Such well-known facts as these do not at first sight point to any highly developed powers of reasoning in the fish, but before drawing any conclusions from them, another factor—that of sensibility—must also be taken into consideration. It is highly probable that a fish hooked with a small flyhook in a gristly part of the jaw feels little or no pain, and therefore if the hook immediately breaks, the fish possibly looks upon it as a very slight inconvenience which in no wise need hinder him from continuing his meal. A fish's brain is a very small mass compared with the weight of the body, and is also small in comparison to the spinal cord. We have no doubt that Professor Edinger will receive many interesting communications from people who are in the habit of studying the habits of fish carefully, and it is to be hoped that some reliable conclusions will be drawn from them.

"DOCTORED" TOBACCO.

WHY is tobacco so often highly scented? Is it not reasonable to suppose that in many cases it is to mask an inferior quality which otherwise would be manifest? That the treatment of tobacco with various essences and flavours is practised there can be little doubt, and every intelligent person knows that in by far the majority of instances the peculiar aromatic flavour of the tobacco he buys does not naturally belong to the tobacco leaf at all. We have strong reasons for believing that the dosage of tobacco with highly scented or aromatic compounds may give rise to real injury to health. This matter becomes the more serious when we consider the large quantity of cheap and nasty cigarettes that are smoked by the small youth of the present day. A correspondent recently forwarded us some cigarettes which were described as having been made from best bird's-eye. They cost 1*s.* 10*d.* per 100, and, as might be expected, were excessively nasty, smelling powerfully of an aromatic substance of a totally different character to tobacco itself. Our correspondent said that they made himself and a friend "feel very queer," and we are not surprised. We are only surprised at his hardihood in risking the trial of such obviously under-priced tobacco. Still, this instance is instructive, and we have been prompted to consult some of those mysterious though useful books which are described to contain "several thousand receipts, covering the latest, most important, and most useful discoveries in chemical technology, and their practical application in the arts and the industries"—in other words, those books that deal with trade dodges, and we have been rewarded with some valuable, if not altogether encouraging, information. Here we find various formulæ for the improvement of inferior qualities of tobacco and for the removal of any disagreeable smell and taste that may characterise them. In these interesting operations we find that the use of the following articles is concerned: orris root, Tonquin bean, juniper berries, coriander seeds, storax, cascarilla bark, angelica root, cinnamon blossoms, badiane, cloves, saltpetre, cassia, glycerine, liquorice root, rosewood, sugar, bay leaves, walnut leaves, green oranges, oil of lemon, amber, vanilla, bergamot, nutmeg, balsam, cardamoms, cubebs, sassafras, galangal, calamus root, &c. It is not improbable that one or other of the substances in this really formidable list, especially if used in excess, would, when submitted to destructive distillation in the pipe or cigarette, give rise to volatile products of a much more injurious character than those due to the combustion

Hosted by Google

of pure, unscented tobacco. At any rate, it is probable that the objectionable effects described above were due to flavouring agents or to bad tobacco. We are aware, of course, that tobacco must to some extent be treated in order to be presented in a smokeable form, but need this process go any further than depriving the leaves of their stalk and moistening and pressing them prior to cutting? Of one thing we are confident, and that is that a large proportion of the smoking public would prefer to smoke pure, unsophisticated tobacco in preference to the stuff that is highly loaded with foreign flavouring substances. Tobacco leaves without any manufacturing process afford a pleasant and enjoyable enough smoking mixture that is infinitely superior to many manufactured kinds as long as specimens of various growths or of various degrees of strength are mixed in suitable proportion to meet individual requirements. It was the original leaf which Sir Walter Raleigh smoked, of which Charles Kingsley said "divine in a pipe, glorious in a hookah." Why cannot the public obtain the next best substitute—that is, an absolutely unsophisticated tobacco leaf, which has only been treated in order to facilitate its being cut up into suitable form?

FUNCTIONS OF THE LUMBAR CORD.

IN the Proceedings of the Royal Society there is an abstract of an interesting paper by Dr. Page May describing a series of investigations into the segmental representation of movements in the lumbar region of the mammalian spinal cord. The method mainly followed was that by excitation of nerve roots and also of the spinal cord, and as a means of controlling the observations with this method mechanical stimulation (pinching, &c.) was sometimes employed in examining the nerve roots. The dog and the monkey were the animals chiefly experimented upon, and in the dog the excitable area of the cord surface was found to be the postero-external column. Stimulation of Goll's column produced no movement except in the lower lumbar region, where that column is very small or absent, and where the effect was probably due to the stimulus directly affecting the fibres of the postero-external column. The movements, as a rule, were limited to the side stimulated, and movements in the lower limb could be produced by stimulation of Burdach's column from the upper border of the thirteenth dorsal segment to the lower border of the first sacral segment, and the areas, stimulation of which produced movements of limbs, arms, and tail, overlapped one another, the hip area, however, being nearer the cerebrum than the knee area and the knee area higher than the foot area. When the cord was transversely divided above the lumbar enlargement the movements were more easily elicited. It was also found that the point, stimulation of which gave movement of the tail, was placed internal to the point for the hamstrings, this again internal to that for the hip, while most external of all was that by stimulation of which movement of the side of the trunk was elicited. Stimulation of the nerve roots gave very interesting results. Stimulation of an anterior root gave, on the whole, a quick, powerful extension of the whole limb; excitation of the corresponding posterior root resulted in flexion of the whole limb. This result was quite constant, and by many facts it seems to be evident that the path along which the impulses pass, as evidenced by movement elicited in stimulating a certain posterior root, is directed towards a point *below* the level of that posterior root, and not, as might be supposed, in the same segment or above it. The same general results were obtained by stimulation of the spinal cord and nerve roots in the monkey. The area found excitable was the postero-external column, stimulation of which, from the thirteenth dorsal to the second sacral segment inclusive, produced lateral flexion of the spinal column, flexion and adduction of the hip, flexion of the knee, ankle, and toes, and movement of the tail and perineum, and peristalsis. And it was also quite definite that the area, stimulation of which produced movement of the tail, was nearer the middle line than that for the hamstrings, while this area was nearer the middle line than that for flexion at the hip, and so on. The same general effects as in the dog were obtained by stimulating the anterior and posterior nerve roots. The conclusions arrived at are: (1) that any reflex centre derives its chief afferent impulse from a nerve root entering the cord, as a rule, about two segments higher; (2) the fibres of the postero-external column are arranged in a definite order from within outwards, the innermost representing the most distal part of the tail; and (3) stimulation of anterior roots in the dog produces extension, of the posterior roots flexion of the limb as a resultant movement. In the monkey there is not this apparent antagonism, because stimulation of anterior roots brings out a differentiation of flexion and extension, although stimulation of the posterior root gives flexion alone. The paper, as will be seen, forms a valuable contribution to the physiology and anatomy of the spinal cord, and we await with interest the study of the results of similar methods applied to the investigation of the cervical and upper dorsal cord.

PLAGUE, PESTILENCE, AND FAMINE.

IT is a sad falling together of events that the sixtieth anniversary of Her Majesty's useful and beneficent reign should see her splendid Eastern Empire threatened so terribly and tried so sorely. "From plague, pestilence, and famine ..... Good Lord deliver us," is a sad appeal to accompany the universal prayer that is being said this year for the Queen's Most Excellent Majesty, and we feel certain that the kind heart of our Sovereign Lady must feel that this is so. More than a million and a half of our Indian fellow-subjects are in receipt of famine relief at the present time, and although the subscription that has been opened here is being nobly supported, it is inevitable that much terrible misery should go unalleviated. Upwards of £120,000 has been subscribed already (Thursday) and several provincial centres are imitating with successful generosity the movement inaugurated by the Lord Mayor of London. The cause needs no urging upon our readers. Famine and the ills that follow in its train do not require detailed description before their horrors can be comprehended. But much can be done by prompt and orderly action. Let our Indian Government be placed at once in possession of a large sum of ready money, and we know that all human means of arresting the march of evil will be at once employed.

SO-CALLED NON-POISONOUS DISINFECTANTS.

NOT a few cases have been recorded of late of death following upon the swallowing of tar acid mixtures described as non-poisonous. An important case was recently reported from Huddersfield in which it appears a woman took a large quantity of a compound called "germol," which is supplied by a Huddersfield firm of manufacturing chemists. On this occasion the "germol" was contained in a bottle marked sanitas. The evidence at the inquest led to the verdict that death was the result of asphyxia produced by corrosive poison contained in a disinfectant called crude "germol." "Germol," however, as we find from a small specimen submitted to us, is described on the label of the bottle as non-poisonous and for external use only. We have pointed out before that manufacturers are not justified in calling these fluids non-poisonous. It may be perfectly true that they have not the

Hosted by Google

same powerful poisonous action as carbolic acid, but still they are poisonous, as in the above instance, in moderately large doses, and therefore it would be more correct to describe them as less poisonous than carbolic acid. There are a great number of similar preparations of this kind in the market at the present time, all of which the public are led to infer are quite non-poisonous. They consist of an alkaline mixture of the phenol derivatives of coal tar. It seems to us that if carbolic acid is to be scheduled as a poison these preparations, which are of a kindred character, should be included, for we have already received sufficient evidence to justify such a course.

NATURAL AND ACQUIRED IMMUNITY.

THE natural immunity of many animals to certain diseases, even when the actual virus is injected, has long been known and various explanations have been given. Quite recently careful investigations have been carried out by MM. Calmette and Delarde in the Pasteur Institute at Lille. In their experiments they made use of the following poisons—viz., an animal virus, serpent's venom, and a vegetable poison, abrine, prepared by macerating jequirity seeds (Abrus precatorius) in water. They found that the immunity of pigs and hedgehogs to venom and of fowls and tortoises to abrine could not be due to the presence of antitoxins in the blood previously to inoculation, for the serum of the normal animals had no protective effect on susceptible animals, nor had it any neutralising effect on the poison when mixed with it outside the body before inoculation, in both these respects differing from serum containing antitoxins. They were also unable to discover any antitoxic substance in the brain, liver, spleen, or other organs of the normal animals. They hold, therefore, that the antitoxic serum is independent of immunity, since that may exist when no antitoxic properties are possessed by the serum. They attribute both kinds of immunity to special characters of the cells of the body.

THE SOCIETY OF PUBLIC ANALYSTS.

THE Society of Public Analysts has now been in existence some twenty-two years and the progress which it has made during that time is a fact upon which it may be warmly congratulated. Though it is an institution which seldom comes prominently before the public notice, yet it is none the less an important one in contributing work devoted to the public service. By means of its monthly publication, the *Analyst*, public analysts in all parts of the kingdom are brought into touch with new developments of fraud and are made acquainted with improved methods of analysis which must be employed in the difficult task of combating new tricks. Of late years the society has been engaged very closely on the question of reform in regard to the present Food and Drugs Act, and their work has been of the greatest possible assistance to those appointed by the Legislature to inquire into the subject, and so much so that practically the recent report of the Food Products Adulteration Committee proved to be in substantial agreement with a draft Bill which was approved and drawn up by the society before this committee commenced its inquiry. From the memorable days of THE LANCET Commission, when the Founder of this journal showed how awful was the nature and extent of adulteration going on, a marked change for the better in the quality of the food supply took place, an improvement which was subsequently subject to control by Act of Parliament. The Act of 1878 is still in force, and it is no matter for surprise that that Act is not found adequately to meet the requirements of food control in the present day. There is no doubt that though people may not be poisoned they are still cheated, not perhaps to the same appalling extent as heretofore, but still, according to the recent Local Government Board returns, "the nature, substance, and quality of the article demanded" by the public fall short to the extent of 10 per cent. of those examined. The proportion of adulteration, however, is probably a good deal higher and many offenders escape. This is due in a very large measure to certain unsatisfactory clauses in the Act with which recent legislative inquiry has been concerned with a view to amendment. This inquiry had its origin in the strong representations calling for repeal made by the Society of Public Analysts, and the good work it has done and is doing in this connexion bears a resemblance to that which the Founder of THE LANCET carried out when he instituted his successful crusade against food adulteration. As might be expected, the proposed new legislation directed towards the more satisfactory suppression of the adulteration of food and drugs, was a subject considerably in evidence in the speeches delivered at the twenty-second anniversary dinner of the society, which was held at the Criterion Restaurant on the 13th inst. The chair was occupied by the newly-elected President of the Society (Dr. Bernard Dyer), who has succeeded Dr. Thomas Stevenson. Among those present were Mr. Kearley, M.P., the Secretary of the Board of Agriculture (Mr. Elliott), the President of the Chemical Society (Mr. A. Vernon Harcourt, F.R.S.), the President of the Institute of Chemistry (Dr. Russell, F.R.S.), the President of the Pharmaceutical Society (Mr. Walter Hills), the Chairman of the London Section of the Society of Chemical Industry (Dr. Messel), the President of the Institute of Brewing (Mr. A. C. Tanqueray), and Professor H. E. Armstrong, F.R.S. The toast, "The Houses of Parliament," was to have been responded to by the Earl of Winchilsea, but in his absence Mr. Kearley, M.P., made suitable acknowledgement, and he congratulated the society upon the admirable assistance it had lent to the members of the recent committee. Professor Thorpe, the Director of the Government Laboratories at Somerset House, replying for "The Various Government Departments," said it would be their endeavour as referees to work harmoniously with the public analysts. The toast of "Our Guests" was responded to in a humorous speech by Mr. J. Fletcher Moulton, Q.C. We observe that no mention occurs in the Queen's Speech of the proposed new legislation, and Mr. Kearley intends to move an amendment to the Address regretting that no intention is expressed in the Speech of promoting legislation in furtherance of the report of the Select Committee on Food Products, which disclosed the existence of unfair and nefarious competition with native food producers by foreigners and others, to the great detriment both of the commercial and agricultural interests of the people of the United Kingdom.

JUSTICES' MEDICINE.

A CASE tried recently at the Limerick Quarter Sessions before His Honour Judge Adams elicited some remarkable views from the bench upon infection, bacilli, and kindred subjects. The medical officer to the Croom Union sued a baker who supplied the workhouse with bread for a certain sum of money due for medical attendance. Among other matters, it came out in evidence that the medical officer had suspended the baker from supplying bread because of the presence of whooping-cough—or, as they call it there, chin cough—in his house. Not knowing any of the circumstances we do not propose to comment upon this action of the medical officer, but what we do take exception to are the remarks with which the judge is credited by the local paper. His Honour is reported as saying: "The doctors went on about the bacilli until they were perfectly mad in their fear. ..... Some time ago he had a physician on the table, and when he was handed the Bible he took it with great care, opened it, and kissed the inside

Hosted by Google

leaf. In reply to him the witness said he was afraid of microbes, vacilli, and micracocci (*sic*) (laughter). But he was not afraid of alcohol, for he was blind drunk and in the opinion of the court in a pronounced stage of delirium tremens at the time (laughter)." This sort of stuff may pass for humour in Ireland, but if so the deserved reputation of the Irish for humour must have been sadly over-estimated. Adams is, however, not an Irish name, and we should be obliged to his Honour to inform us why, if the physician was "blind drunk," he permitted him to be sworn? There is a very real danger in kissing a book or anything else that is constantly being kissed by the class of persons frequently to be found in law courts, and the equally impressive and binding Scotch or mediæval form of oath-taking is much preferable to the form at present in use.

THE REMOVAL OF INFECTIOUS CASES IN PUBLIC CONVEYANCES.

A REMARKABLE case has recently been investigated by the East Grinstead (Sussex) Urban Council concerning the removal, by the medical officer's orders, of cases of a diphtheritic nature to hospital in a public conveyance. The matter was brought to the notice of the Local Government Board, who forwarded the letter of complaint to the council. The medical officer reported that the cases in question, being those of membranous croup or diphtheria were removed to the cottage hospital in a cab, every child being enveloped in a clean blanket, and the distance travelled being only half a mile, so that, in his opinion, there was no risk of contaminating the cab. The committee came to the conclusion that in their opinion any case where there was the least suspicion of infection should not be removed in a public conveyance, but in the proper ambulance provided for the purpose. In this view the council concurred, and it was agreed to send the reports to the Local Government Board and to apply to the guardians for leave to use their ambulance in case of emergency.

CONGENITAL ABSENCE OF PATELLÆ.

CONGENITAL absence of both patellæ is a rare phenomenon, and a paper by Dr. A. T. Bristow of Brooklyn, in the *Medical News* of New York of Jan. 2nd of this year, is therefore of considerable interest, containing as it does a report of such a case illustrated with excellent skiagrams, and a *résumé* of the small amount of literature which exists on the subject. In the case under Dr. Bristow's care the child was brought to the Long Island Hospital in the summer of 1895. The patient was a boy, two and a half years old. He had a slight pes varus of the right side and a severe type of the deformity on the left which evidently called for operative interference. While examining the child for the purpose of correction Dr. Bristow's attention was attracted to the case with which a luxation of the knee could be produced. Indeed, at first the peculiar crack with which the dislocation occurred most unpleasantly suggested a fracture. Closer inspection revealed the fact that the knee-joint on each side immediately became dislocated on bringing the axes of the femur and tibia into line, and that the bones could be displaced in any direction almost at will. As the joint looked peculiarly prominent the condyles were examined, and both patellæ were found to be absent. The tendon of the quadriceps, instead of being thick and strong, was very thin, and was spread out over the front of the joint, seeming to be attached in part to the condyles of the femur, as well as to the fibula and tibia. There had been no attempt on the part of nature to supply a patella. There have been cases reported where this bone consisted of a rudimentary cartilage, but there was nothing of the sort to be found by palpation in this case. The most complete account of the cases reported may be found in a paper by Hartigan in the *National Medical Review*, 1879, vol. i., p. 92, but other cases have since been published. In all the cases on record there seems to have been an element of spasm or a contracture of the quadriceps, as it always required more force to bring the limb from its position of extreme anterior flexion backward during the first part of the arc than the last, and much flexion of the limb, or lateral motion, was painful. In many of the cases there seems to have been a nervous element present as a factor in producing the accompanying peculiar deformity in these patients; but it is possible that this was reflex and in the direction of protecting the joint, for the synovial surface would be most exposed in extreme flexion and best protected in anterior flexion. All the cases, without exception, seem to have been subject to other developmental errors, a rule to which the case recorded by Dr. Bristow was no exception, as the patient had a varus on both sides. The skiagrams showed that the tibia on the right side was dislocated outward and backward, with a rotation of the femur inward and the tibia outward. The bones were much more closely approximated in this limb than on the left side, as is evidenced by the skiagram. The inter-condyloid notch on the left side seems much more marked than on the right and the profile of the tibial joint line is more curved.

THE PORTSMOUTH ASYLUM MEDICAL STAFF.

AT the meeting of the Portsmouth Town Council a reference was made to the medical staff of the asylum, it being mentioned that an assistant medical officer had been appointed at a salary of £100 a year and the asylum committee recommended a third at £70. Mr. Emmett congratulated the committee especially on having obtained the services of a qualified medical man with eight years' previous experience at £100 a year. He said it was disgraceful to ask a professional man to accept such a salary, and added that he hoped the committee would think it wise to revise their salaries, for there was a vast difference between £100 with eight years' experience and £600 with no experience at all. On an alderman protesting and saying that the officer got board, lodgings, and washing as well, Mr. Emmett quoted from THE LANCET similar appointments where the sum of £225 was offered. However, nothing was done, the council probably consoling themselves with the suggestions that the place was really worth £250 a year, that the salary was a "progressive" one—we should have thought it decidedly "moderate"—that it would be increased in six months, and that there were seven candidates for the post.

THE MARRIAGE OF FEMALE EPILEPTICS.

IN an instructive note in the *Phonographic Record of Clinical Teaching* Dr. Gowers lays down rules for guidance when the medical practitioner's opinion is sought respecting the marriage of an epileptic female. Commencing with the proviso that the medical man must not decide the question, but content himself with placing before the patient the materials from which a decision can be reached, Dr. Gowers says that to the patient herself marriage and even pregnancy will make little difference, whilst the man who aspires to the hand of an epileptic lady must look to the severity of the disease and the extent to which it threatens mental powers, and must decide for himself whether he will inflict upon himself a wife with such an infirmity. The important question is the influence exerted on future children, and on this the family history, rather than the clinical aspects of the case, will throw most light. In cases which are the result of accidental lesion of the brain, and which are characterised by the severity of the initial convulsions, by their frequent one-sidedness, and by the absence of hereditary taint, fears of inheritance are groundless; but if epilepsy or insanity can be traced in ancestors or relatives the probability is very great that some of the future children will

Hosted by Google

have some neurotic affection. If there are six children the chances are against the escape of all, though at the same time the chances are considerably against any individual child suffering. The stronger the hereditary taint the more likelihood there is of its transmission. The well-being of the community would preclude such marriages, but the well-being of society seldom influences the conduct of the individual; and Dr. Gowers has to confess that in most cases submitted for an opinion the devoted couple take the risks and marry.

THE MUNIFICENCE OF BARONESS HIRSCH.

As the daily press has already mentioned, the Baroness Hirsch has given £80,000 to found a hospital in England for phthisical children. This bequest is not only generous, but, eminently sensible and practical. The scheme as at present proposed is as follows. A hospital is to be built by the sea for the reception of three or four hundred children, an endowed fund supplied, and a convalescent home to be built in addition. This is an admirable scheme, especially if, as we hope is the case, the children are to be housed in separate blocks, containing not more than fifty beds respectively. Pulmonary phthisis is pre-eminently a disease which requires for its treatment fresh air and sunlight, and these two factors are impossible of attainment in large towns. It is very far from our purpose to disparage the well-directed work of the Brompton Hospital, but we are sure its work would be even more valuable if the town house could be used mainly as a feeder for sundry country establishments, for besides the benefit to the patients themselves there would be a diminution in the risk of spreading tuberculous infection, which always must exist when tuberculous patients are aggregated together in urban dwellings. We earnestly hope that this noble example of the Baroness Hirsch may be followed by others who are rich in this world's goods, and that other hospitals for the treatment of convalescent patients may be established in suitable situations.

AUTOPLASTY OF THE PREPUCE AMONG THE ANCIENT HEBREWS.

WHEN Christianity became paramount in Syria the Jews who adhered to their pristine customs were exposed to grievous persecution. The following example of the shifts they were put to in order to conceal their identity is related by Dr. Beugnies of Givet in his work on Circumcision in Palestine, and will be found of interest, not only from an historical, but also from a surgical point of view. "While the Grecian dynasty was supreme at Antioch circumcision went through a crisis which may be described as epic. Antiochus Epiphanes formally forbade the practice with regard to the newly born under pain of death to both mothers and offspring, and at least two women convicted of disobeying the royal edict were cast from the summit of the city ramparts with their infants at their breasts. Numbers of Israelites, anxious to propitiate the good graces of their sovereign master, did not hesitate to attempt the re-construction of their ablated foreskins — *sibi præputia fecerunt*. By this we should probably understand that they ceased the mutilation of their male children, for autoplasty of the prepuce is such a delicate operation that before we can believe in its performance at that early date the most ample proof is necessary." Curiously enough, some time after the publication of his book Dr. Beugnies came across the required proof in a short note which he attributes to Broca. According to this authority, rehabilitation of an excised prepuce was quite a common operation in ancient surgery. *Verpi* in Rome were specially taxed, besides being excluded from the privileges of citizenship, and in order to escape from these disabilities they were willing to submit to the following plastic procedure. In the first place the surgeon made a circular incision round the body of the penis at a suitable distance from the end of that organ and implicating the skin alone. He next detached the latter from its subjacent tissues to within a short distance of the corona, and then completed the operation by everting the ring of skin over the exposed glans, where it formed a more or less perfect prepuce. A highly inconvenient cicatrix was naturally the result of this attempt to remedy man's interference with nature, but apparently the patients decided to put up with this disadvantage for the sake of the substantial benefits that otherwise accrued to them.

THE MILROY LECTURES FOR 1898.

DR. MONCKTON COPEMAN has, we hear, been appointed Milroy Lecturer for the year 1898, and the subject selected for the lectures is the "Natural History of Vaccinia and Variola." The subject is one which seems to us to be an exceptionally happy one for 1898, the year which celebrates the centenary of the publication of Edward Jenner's "Inquiry into the Cause and Effects of the Variolæ Vaccinæ ....." Dr. Copeman is especially well qualified to deal with matters relating to vaccinia, and his valuable researches into the effects of storing vaccine lymph in glycerine are likely to have a very far-reaching influence on the future methods of lymph storage in this country. We shall doubtless have, too, from Dr. Copeman in the Milroy Lectures a full account of his interesting investigations into the bacteriology of variola.

THE REGISTRATION OF NURSE CHILDREN.

THE Infant Life Protection Act is not so stringent a measure that any legal safeguards for its application can be dispensed with. Chief among these is the obligation to register which is binding upon the custodians of children. In this requirement we possess the only available guarantee against mismanagement or wilful misconduct on the part of such caretakers. A case recently investigated in the North London Police-court at the instance of the London County Council is of interest, not because misconduct was shown to exist, but on account of a remarkable connexion between the most respectable references, an apparently complete oblivion all round as to the requirements of the law in such cases, and, finally, an abnormally high infant mortality. Martha Taylor, a widow, had had under her care since 1892 fourteen infants, eight of whom had died. She was certified to be respectable, was well known in her neighbourhood, but though registrable was not registered and was professedly unaware that she should be. No neglect or ill-usage was proved against her, but it is worth noting that her weekly allowance for nursing each infant and for her own sustenance was but four shillings. She was at last obliged to seek parish relief, and further inquiries led to the investigation referred to. The children, as a rule, were derived from the "rescue homes" of the Salvation Army and were usually illegitimate. Perhaps the constitutional weaknesses which often come of an unknown parentage had something to do with the deaths which occurred among them; but no suggestion of this kind has been mentioned. Other causes at least as powerful must have been at work in the home of a very poor widow struggling to support an infant and herself on four shillings a week. Such a pittance was clearly inadequate for the performance of the duties required of her. Her capacity as a nurse was not discussed at her examination, but we may safely conclude that it was not of the highest order. From whatever point we regard this incident it can hardly be doubted that the introduction of registration and inspection at an earlier stage of her nursing history would have materially improved the prospects of

Hosted by Google

eight children. Not the least singular circumstance about this case is the facility with which the responsible officials of the Salvation Army seem to have accepted as a guardian for their rescued children an unregistered, and therefore a disqualified, person. However fair their intentions, the result is not flattering to their discrimination.

THE HEALTH OF THE QUEEN.

A PARAGRAPH with the above heading and bearing the sub-heading "alarming rumour" has recently appeared in certain newspapers suggesting that Her Majesty is seriously unwell. We are glad to be able to announce on the best authority that the statement in question is absolutely untrue. Her Majesty is in excellent health and her general condition gives no cause for special anxiety on the part of her medical attendants apart from that which naturally attaches to every individual of advanced age. It is most regrettable that circulation should be given to such ridiculous rumours as that to which we refer.

DINNER TO MR. J. H. RUTHERGLEN.

IN recognition of his active and successful exertions which resulted in the passing of the Poor-law Officers Superannuation Act, 1896, Mr. J. H. Rutherglen, chairman of the Superannuation Committee of the Poor-law service, will be entertained at a public dinner on Wednesday, Jan. 27th. Lord Glenesk has consented to preside, and it is to be hoped that the committee which is arranging this well-merited tribute to Mr. Rutherglen's talents for organisation and persuasion will be rewarded by a good attendance of members of every branch of the service and of both sexes.

THE WATER-SUPPLY OF TORQUAY.

THE corporation of Torquay are contemplating a step which might well be followed by the municipal authorities of other places occupying a similar position. For some time they have been considering the question of not only augmenting the supply of water to Torquay, but also of bringing the supply to a standard of higher quality and character. To do this it is proposed to apply for an Act of Parliament for powers to purchase the water-shed from which the water of the town is derived so as to place the administration from beginning to end under the entire control of the corporation. It is believed that the acquirement of this water area, which is situated on a projection of Dartmoor, will provide for an abundant supply of water, not only for existing requirements, but for future demands. Amongst the principal objects for securing the control of this area is the vitally important one of placing the corporation in a position to eliminate all likely sources of contamination. We are glad to find that at the statutory meeting which was held in Torquay on the 15th inst. the council received the sanction of by far the greater majority of those in attendance, so that the necessary way has been cleared for applying for an Act of Parliament

THE EDUCATION OF CHILDREN OF DEFECTIVE INTELLECT.

THE Lord President of the Council has appointed a Committee to report upon the Education of Children of Defective Intellect. The committee is constituted as follows:—The Rev. T. W. Sharpe, C.B., H.M. Senior Chief Inspector of Schools (chairman); Mr. H. F. Pooley, Senior Examiner, Education Department; Mr. A. W. Newton, H.M. Inspector of Schools; Dr. Shuttleworth, late Medical Superintendent, Royal Albert Asylum for Idiots and Imbeciles; Dr. W. R. Smith, Medical Officer of the London School Board; Mrs. Burgwin, Superintendent of Schools for Special Instruction under the London School Board; and Miss Townsend, Member of the Council of the Association for Promoting the Welfare of the Feeble-minded. Mr. H. W. Orange, Examiner, Education Department, will act as secretary to the committee. The terms of reference to the committee are as follows:—To inquire into the existing systems for the education of feeble-minded and defective children not under the charge of guardians, and not idiots or imbeciles, and to advise as to any changes, either with or without legislation, that may be desirable. To report particularly upon the best practical means for discriminating, on the one hand, between the educable and non-educable classes of feeble-minded and defective children, and, on the other hand, between those children who may properly be taught in ordinary elementary schools by ordinary methods and those who should be taught in special schools. To inquire and report as to the provision of suitable elementary education for epileptic children and to advise as to any changes that may be desirable.

THE MEDICO-LEGAL VALUE OF ANTIVENINE IN INDIA.

PROFESSOR HANKIN, director of the bateriological laboratory at Agra, recently had submitted to him cloths which had been removed from the intestines of some cows which had died, apparently, from some acute poisoning. Chemical analysis being impracticable, Professor Hankin macerated the cloths and concentrated the solution obtained. Part of this was inoculated under the skin of a rabbit, which died in less than an hour with every symptom of poisoning by serpent venom. The rest of the fluid obtained from the cloths was then mixed with a small quantity of Calmette's "sórum antivenimeux" and injected into a second rabbit, which showed no symptoms whatever. If this observation proves to be corroborated by further trials, the knowledge that poisoning by serpent venom can be detected by scientific methods may check the use of this agent in India, where it appears to be frequently employed to poison animals. Another agent frequently employed for this purpose is abrine, the albuminoid substance contained in jequirity seeds. A serum antitoxic to abrine has been prepared by Dr. Calmette of the Pasteur Institute at Lille, whose researches on serpent venom are so well known, and it is possible that this also may be of use in finding the exact poison that has been employed and bringing home crime to guilty parties. It is an interesting example of the unlooked-for practical results which often spring from purely scientific laboratory experiments. The whole aniline industry, for instance, arose from the incidental discovery of one of the aniline colours by Dr. W. H. Perkin when carrying out a patient laboratory research in the unsuccessful endeavour to prepare quinine synthetically.

GERMAN COURTESY TOWARDS ENGLISH INVESTIGATORS.

IT would perhaps be hardly correct to say that science recognises no nationality, for the simple reason that friendly international competition has been instrumental in bringing about scientific progress. There is, however, about all honest investigators a feeling in matters of this nature that progress is best attained by freedom of discussion and by mutual help. This spirit has always been especially well marked in Germany, and we hear with pleasure that Dr. Thorne Thorne, the principal medical officer of the Local overnment Board, accompanied by Dr. Monckton Copeman, one of the medical inspectors, while recently investigating the methods of lymph production, storage, and distribution in Germany, have been afforded not only every facility for prosecuting their inquiries, but also have received at the hands of the nation's representatives the most generous hospitality. Germany has nothing to fear in revealing the very scientific

Hosted by Google

methods adopted in this particular, but it is nevertheless very gratifying to learn at the present time of representatives from this country being so graciously received. We can only trust that when investigators from Germany next visit our shores on anything like a similar mission that equal facilities and hospitality will be extended to them. We believe, too, that in France and Belgium Dr. Thorne Thorne and Dr. Copeman were accorded every opportunity for observing the methods of lymph production. The result of this mission is not yet known, but it is quite certain that no one could study the excellent practices in vogue in Germany without coming to the conclusion that in England we have yet much to learn in the matter of lymph production and collection; and we shall be much surprised if this inspection of Continental methods does not lead to very material alterations in the production and storage of lymph in this country.

WHILE considerable satisfaction is expressed at the fact of a promise being given in the address from the Throne that a Bill will be submitted to Parliament to improve the arrangements for water-supply in the metropolis, and a Bill also to make better provision for the compensation of workpeople who suffer from accidents in the course of their employment, yet it is a matter of surprise and some disappointment that there is no indication of any immediate steps being taken in regard to the recommendations of the Food Products Adulteration Committee, whose difficult task was finished and whose report was printed some months ago. We understand that this omission will form the basis of an amendment by Mr. Kearley, M.P.

ON Wednesday last, Jan. 20th, Lord Lister was presented in Queen's College, Belfast, with an address from the Members of the North of Ireland Branch of the British Medical Association. The occasion was the opening of the new physiological, pathological, and bacteriological laboratories. In an address which Lord Lister delivered he dwelt upon the advantages which would accrue to medical practitioners by the establishment of central stations where they could send specimens for examination and report.

WE have received a circular from the Guy's Hospital Out-Nursing Fund asking for pecuniary support. The Out-Nursing Fund is a scheme for the nursing at their own homes of convalescent patients from the wards and out-patient department of the hospital. The honorary secretary, who will receive subscriptions and give all information, is Mr. C. L. Josephs, of Broxbourne, Herts.

THE Secretary-General of the Twelfth International Congress of Medicine to be held in Moscow next August has announced that June 1st has been fixed as the last day upon which particulars, titles, and abstracts of communications to be read to the Congress can be received by the executive committee.

IT is with great regret that we announce the death of Dr. Edward Ballard, F.R.S., late medical inspector of the Local Government Board, at his residence, Ravenscroft Park, High Barnet, on Tuesday morning last. We must defer till next week a full notice of his useful and distinguished career.

THE Queen has re-nominated Mr. William Moore, M.D.Dub., Physician in Ordinary to Her Majesty in Ireland, to be, for five years from the 25th inst., a Member of the General Council of Medical Education and Registration of the United Kingdom, for Ireland.

THERE will be a public meeting at the Drill Hall, Cheniesstreet, W.C., on Thursday, Jan. 28th, at 8.15 P.M., to direct public attention to the serious financial condition of University College Hospital. The Duke of Bedford will preside.

AT the general meeting of the Royal Meteorological Society held on the 20th inst. Dr. Theodore Williams, late President, and Dr. Robert Barnes, late Vice-President, were elected members of the Council of the Society.

THE Duke of Connaught will preside at the Biennial Festival of the National Hospital for the Paralysed and Epileptic (Albany Memorial), Queen-square, Bloomsbury, on March 24th.

LORD GLENESK will take the chair at the annual dinner of King's College Hospital, to be held on May 14th, in the Whitehall Rooms of the Hôtel Métropole.

WE have received the Army Medical Report for 1895, but are compelled to defer notice of it until next week.

IRISH POOR-LAW MEDICAL RELIEF SYSTEM: ITS ORGANISATION AND ADMINISTRATION.

BY PATRICK LETTERS, M.D. ABERD., D.S.M. IREL.,
MEDICAL ATTENDANT TO THE STAFF OF THE ANGLO-AMERICAN TELEGRAPH COMPANY, VALENTIA, IRELAND.

THE subject of Irish Poor-law Reform is one to which a large share of public attention has been recently directed, both in the lay press and in medical journals. The exposure of grave irregularities, or, as some of the more pithy writers put it, of barbarities and abominations, has led to the formation of the Irish Workhouse Reform Association—an influential organisation which has set itself to the herculean work of rectifying long-established abuses. Enough has been disclosed to justify this effort to ameliorate the lot of the poor who are forced to seek the shelter of these institutions, and no philanthropist can withhold his sympathy from the movement. It is not my purpose, however, to discuss the mismanagement of Irish workhouses, but to direct attention to that branch of the Poor-law system administered directly by the medical profession, the medical relief department of the Irish Poor-law service. This I purpose discussing from several standpoints, thus: from that of a medical man unconnected, but thoroughly conversant, with the service; from that of the sick poor directly affected by it; and from that of the public, whose interest in it should be a practical and profound one. To understand fully the case of the Irish poor-law medical officer one must live in Ireland and learn by observation the conditions under which official work is carried out, the whole surroundings of the medical man being so unlike those existing in the other divisions of the kingdom.

The Irish Poor-Law Medical Relief Organisation is planned upon a comprehensive basis. The country is mapped out into 159 unions, each of which is sub-divided into a varying number of dispensary districts, usually from four to six, in accordance with the extent of the union. The number of these dispensary districts in Ireland is 721, and their distribution in the provinces is, for Ulster, 214; Munster, 206; Leinster, 202; and Connaught, 99. The workhouse is a central institution, receiving its inmates from the different districts. Besides affording an asylum to the aged and destitute it contains wards for the treatment of medical and surgical cases, also for infectious fevers when a separate isolation hospital is not provided, and there is usually some accommodation for lunatics and idiots. Each dispensary district is officered by a separate medical man. The workhouse medical attendant may, and often

Hosted by Google

does, in addition, hold an appointment to one of the dispensary districts, and in large urban workhouses a resident and several visiting medical officers are required. The total number of medical officers in the poor-law service is 813, distributed thus: in Ulster, 238; Munster, 232; Leinster, 229; and Connaught, 114. The sanitary appointments under the Public Health (Ireland) Act are held by the dispensary medical men, who are medical officers of health for their respective districts. The workhouse medical officer is usually, though not necessarily, the consulting or superintendent medical officer of health for the whole union. The dispensary medical officer's work may be estimated by striking average figures for the whole country embracing the following points: (*a*) population, (*b*) area, and (*c*) valuation. Calculated upon official figures the population of an Irish dispensary district is found to be 6525; the area in acres 28,194, equivalent to 44 square miles; and the valuation, in round numbers, £20,000, or exactly £19,658. If the four provinces be separately analysed certain differences are brought out which it is well to remember when estimating to what degree the existing system has succeeded, or is still capable of fulfilling the orginal object of relieving the sick poor on the one hand, and of dealing justly by the medical officers on the other. It is found by calculating averages for the four provinces that the population of a dispensary district in Ulster is 7569; in Munster, 5691; in Leinster, 5880; and in Connaught. 7321. The areas of dispensary districts average—in Ulster, 24,870 acres; Munster, 28,809; Leinster, 23,944; and Connaught, 42,769. To enable the extent to be better grasped these acreage areas reduced to square miles give for Ulster, 39; Munster, 45; Leinster, 37; and Connaught, 67. The next set of figures is the valuation, from which approximately the resources on which a dispensary medical man has to depend to supplement his official salary may be deduced. The average valuation of an Ulster district is found to be £21,343; and of a Munster one, £16,616. In Leinster the figure stands at £23,687; and in Connaught at £13,823.

I now come to the consideration of the official figures showing medical relief work accomplished. This comes under two heads—(*a*) medical attendances and advice at dispensaries, and (*b*) visits to patients at their own homes. The same form of ticket authorises all attendances, advice, or visits, but that requiring attendance at the patient's own residence is printed in red type for distinction, and the familiar "red ticket" is always understood to imply some urgency and that the patient is unable to appear personally at the dispensary station. The medical officer's attendances at the dispensary are at appointed and fixed hours and days, usually twice or thrice weekly where the district contains one station only, or once or twice weekly at each station where for the convenience of the poor two stations have been fixed in the district. Before concluding I shall discuss the alleged abuse of these red tickets, and shall advert to a recent interview between the Chief Secretary for Ireland and a deputation from the Irish Medical Association, representative of the dispensary medical officers, the object being to obtain the redress of certain grievances under which the Irish Poor-law medical officers are said to suffer. In the meantime I must supply figures for medical relief work done. Taking all Ireland again into account and striking an average each dispensary medical man in one year affords medical relief to some 805 cases, not necessarily separate patients, but to that number of distinct illnesses treated to a conclusion. Some of these will give the practitioners no further trouble than a single attendance for advice and medicine at the dispensary station, others will attend on several occasions, while the visits at the patients' homes will be solitary, few, or several, in accordance with the nature of the case, the medical man's responsibility not ceasing until the termination of the case either in recovery, removal to hospital, death, or failure of the patient to attend at the dispensary station, if able to do so. As red tickets form the really laborious part of a medical officer's duty by necessitating often long journeys through bogs and across mountains, I will confine myself to these, leaving the amount of advice-giving and medicine-compounding work at the dispensaries to be understood. Well, taking the average again for the whole country, each dispensary medical officer treats 243 cases annually under red tickets. In Ulster the average is 291; in Munster, 228; in Leinster, 286; and in Connaught, 152. The marked difference between Connaught and Leinster does not prove healthier conditions to prevail in the former province than the latter—it simply indicates the fact that red tickets are issued with greater restriction in Connaught.

[Dr. Letters here criticises the association of poor-law and public health duties in the same individual. He continues:]

What, then, are the grievances which the Irish dispensary medical officers seek to have redressed? As formulated by a representative medical deputation which recently waited on the Chief Secretary for Ireland, they want all abuses of the Poor-law medical relief system to be redressed, they ask pensions to be provided for retiring Poor-law officers, and they call for an improvement of the existing salaries. Mr. Balfour replied to all the points brought under his notice, but failed to satisfy the deputation. In regard to abuses to be redressed, it is worthy of remark that some of the most flagrant of these were not mentioned, and the Chief Secretary's statement, therefore, was limited to the points brought forward to show the injustice and hardship which, according to the dispensary medical officers, operate against them. Replying to the application for increased salaries Mr. Balfour adverted to the fact that the average income of dispensary practitioners from official sources amounted to £171 annually, but at the same time admitted that even were this supplemented by reasonable earnings from private practice the income would be insufficient to maintain an officer and his family in respectability. The income from private practice of dispensary medical men in Ireland is, of course, unknown, but must vary considerably in urban and rural districts as well as in different counties. It may be assumed, on the whole, that it falls short of that of the general practitioner in wealthy and populous England. To make things level the Irish practitioner is obliged to charge higher professional fees than his English *confrère*. Owing to the practical monopoly which his appointment secures him in his own district his demands are not questioned if made upon a moderate scale. Should he, however, attempt in any rural district to enforce the proverbial guinea fee, that can only be complied with in exceptional cases of emergency and indirectly leads to an abuse of the red ticket system, for which there is no one to blame but the medical man himself.

Let us now turn to the red tickets to see in what ways they are abused. They are said to be indiscriminately issued, that books of tickets are signed by the authorised person, but left with shop assistants and others to fill up, who in turn distribute them regardless of the suitability of the applicant for relief. In some cases the tickets are not even signed; in others they are issued without any request from the patient or even against his wish. It is further complained that house-owners issue these tickets unsolicited in order to clear out a case of infectious disease from the premises. It is again said that tickets are issued, not for medical relief, but as an indirect means of procuring out-door relief, &c., for applicants who are quite able to pay ordinary fees, and who are perhaps at the time actually paying fees to another practitioner. Another example of alleged abuse is the issue of tickets to persons dead or dying, when treatment would be useless, and simply to procure a death certificate. The list of irregularities concludes with a statement that tickets are sometimes served upon medical officers by post, in contravention of the regulations. This is the red ticket grievance, as formulated by a letter from the Irish Medical Association to the Local Government Board for Ireland, dated July 31st, 1896.

It will occur at once to those of my readers who have made a special study of State medicine that the tabulated statement of red-ticket grievances is not so solid as it appears. The primary object of the Medical Charities Act, as set out in the preamble to the Act itself, is to provide for the better distribution, support, and management of medical charities in Ireland and to amend an Act of the eleventh year of Her Majesty to provide for the execution of the laws for the relief of the poor in Ireland. It is irrational to expect the Chief Secretary to shut his eyes to his primary duty to the poor in the administration of this Act. It is equally absurd to expect him to forget that which as a statesman he must instinctively feel—viz., that in all such questions he must weigh carefully how much of the country's interests are involved and affected thereby.

Let us just take a glance at the red-ticket abuses from a public health point of view and perhaps we may find some justification for Mr. Balfour's attitude. It is alleged that tickets are issued in the case of dead and dying persons. An assumption is here made that as treatment would be useless it is an abuse to issue a ticket. On such

Hosted by Google

a question I do not hesitate to maintain an opposite opinion. Uncertified deaths must be expunged from our national registers as a serious evil, and medical statisticians everywhere should rigidly oppose anything tending to perpetuate these blank records. Rather, therefore, than that this entry should appear in registration, "Death not certified—no medical attendant," let the red ticket be abused—the end justifies the means. It cannot be a frequent occurrence for a house-owner to issue a ticket irregularly for the sole purpose of clearing out an infectious case from his premises, and when it does occur I should justify it on the ground of public health. It is a smaller evil to inflict a trifling injustice on a dispensary medical man than to kindle a flame of epidemic disease in the district. I fail to see the slightest hardship in the service of a red ticket by post. The spirit of the Act is to offer every facility for attendance on the poor, and the regulations properly specify that red tickets may be served upon the practitioner at all times and places. To interfere with this would be to cut at the root of the Act, and the more general employment of rural postmen in Ireland to convey dispensary messages would be advantageous to all parties, and I should think oftentimes most convenient for the medical man. I should regard it as an abuse of red tickets when they are issued for the sole purpose of obtaining out-door relief and without a medical reason. If this form of abuse were at all common I presume more would be heard about it, as dispensary medical officers in such cases, by an appeal to the dispensary committee of management, could, and would, expose the fraud sufficiently to have it abated. There is another form of abuse not mentioned in the letter of the association, but which occasionally occurs. It is this: a dispensary medical man is unfortunate enough to incur the hostility of an unscrupulous member of his committee, who, through pure malice and under cover of his powers, may issue tickets entailing quite unnecessary journeys upon the medical officer. The occurrence is, I should think, exceedingly rare, but when red tickets are abused in this manner the practitioner becomes at once an object of well-merited sympathy—he has a real grievance.

[Dr. Letters here gives a very unflattering description of the manner in which elections to Irish workhouse and dispensary appointments are conducted. "There are more serious irregularities and abuses in connexion with dispensary election contests in Ireland than in any other department of public service into which competition enters." "The electoral bodies are—for workhouse appointments the board of guardians, which have usually from thirty to fifty members, and for dispensaries the dispensary committees, annually elected by the guardians." He continues:]

The Local Government Board cannot but be cognizant of the main features of these evils, and ought to be able, with their powers, to apply a remedy. It may be that the magnitude of the evil is not understood, and yet a strong case exists for interposition of some kind. It is well known that by-laws are often more determinate and prescribe rules with more binding effect than a general statute. Under the Public Health Act convictions are more readily obtained for offences against by-laws, which introduce a question of fact only, than under the sections of the Act itself. Similarly, were the Irish Local Government Board, by departmental regulation, to try the experiment of having some practical share in these elections, the interests of the sick poor and of the general public would be alike advanced, scandals and exhibitions degrading to the medical profession would be prevented, the whole tone and status of the Poor-law medical service would be improved and elevated, and the elected men would enter on their duties with a fuller measure of public confidence than men appointed without regard to professional merit.

It may be felt that this article is incomplete without the offer of something definite and specific in the way of remedy. As a ten years' observer of the working of the Irish Poor-law medical service I feel quite safe of my position in directing professional attention to these defects in its administration, but I would not feel equally sure of the propriety of pressing forward my own individual conclusions as to the correct line of reform. That I have not been a personal witness of the system without coming to definite well-digested ideas, both as to the best remedies to apply and as to the most prudent method of their application, may be inferred. This does not, however, undo the fact that my conclusions are only those of an individual, nor would it entitle me to usurp functions which others are officially commissioned to discharge. The Local Government Board for Ireland has supreme control over the service. Its President, the Chief Secretary to the Lord-Lieutenant of Ireland, is not a minister of health, but he need not go outside the department for any assistance or direction in medical administration. An experienced medical commissioner and a staff of efficient medical inspectors are at his command.

THE JENNER CENTENARY IN RUSSIA.

THE commemorative meeting of the Russian National Health Society in honour of Jenner and the hundreth anniversary of his great discovery was, it may be remembered, to have been held in May last. The Coronation of the Emperor in that month caused the postponement of the celebration until October, and various other causes led to its still further postponement, so that it was not until Sunday, Dec. 22nd, Old Style (Jan. 3rd), that it was finally held. These successive delays, while they were unfortunate from one point of view, had the advantage of allowing the society plenty of time for preparation and of enabling it to gather from all quarters of the earth an exceptionally interesting and representative collection of objects, which for the present remain on view to the public in what is called the "Vaccination Exhibition." The name of Jenner, it will be noticed, has dropped out of the name of the exhibition; but the man himself is very much *en évidence* on the walls and in the glass cases in the Medical Department of the Ministry of the Interior (where the exhibition is held), and the commemorative meeting was one prolonged eulogy of our famous fellow-countryman. That meeting, which was held in the hall of the Medical Department, was a most enthusiastic one. The hall was effectively draped and decorated with palms and other plants. As is customary at all public functions in Russia, busts of the Imperial family occupied prominent positions, but the post of honour was given to a bust of Edward Jenner, the hero of the day. This bust was modelled by a young Russian sculptor from portraits of Jenner, and he has caught with great success the characteristics of his features as they have been handed down to us by Lawrence, Northcote, Smith, and others. At two o'clock the Grand Duke Paul Alexandrovitch, who is honorary president of the National Health Society, entered the hall, while the band played the National Anthem. With him came the Prince and Princess of Oldenburg, two Ministers of State, M. Durnovo, the President of the Committee of Ministers, and M. Goremuikin, the Minister of the Interior, and several other high officials and representatives of medical and scientific institutions who were the guests of the society for the occasion.

After a brief speech by the Grand Duke, who presided over the meeting, Dr. Kudrin, acting president of the society, drew an interesting picture of the change which Jenner's introduction of vaccination had wrought on the incidence of small-pox in Russia. In the course of his speech he said that in the last century, when the population of the country was only 40,000,000, the number of deaths from small-pox each year was at least 200,000. Certain tribes in Siberia had been completely killed off by the disease. He closed his speech by a tribute of praise to Dr. Hubert, who had proposed and organised the present meeting and exhibition, and to whom, in conjunction with Dr. Ragozin, the Director of the Medical Department, the success of both was entirely due.

The next speech was an eloquent eulogium of Jenner pronounced by Dr. Lukianof, the Director of the Imperial Institute of Experimental Medicine (formerly the Oldenburg Institute). The speaker dwelt on the immense significance of Jenner's work. Not only had it saved millions of lives in these hundred years, but it had been of incalculable scientific value. He was the model scientific worker. By his thirty years' careful experimental work he had incontrovertibly proved the value of vaccination. Long before bacteriology was known he had established the principle of preventive inoculation and had thus rendered possible the scientific advances of the present century in this great branch of medicine. He led the way which Pasteur and others had so successfully followed in investigating the subject of immunity.

When the applause and cheers with which this speech was received had subsided Dr. Kormillo ascended the rostrum and gave a historical sketch of the introduction and gradual

Hosted by Google

spread of vaccination in Russia during the last hundred years.

The results of the competition for the prizes offered by the society were announced by Dr. Lukianof. A large gold medal was awarded to Dr. Alexandre Layer of Bordeaux, the author of an essay entitled "A la Mémoire d'E. Jenner"; another large gold medal to Dr. Miller, the principal physician to the Foundling Hospital in Moscow, for his handbook on Vaccination; a small gold medal to Dr. Glagolef, a *zemski vratch* (or medical officer of health); and silver medals to Dr. Deloble and M. Kazet, a veterinary surgeon. Of the thirty-two works sent in for competition the majority were of course in Russian; of essays in other languages the English were the most numerous, but unfortunately none of these gained a medal. The society's gold medal and sum of 1000 roubles which had been offered for the best work sent in were not awarded.

The representatives of a number of Russian medical societies and institutions then either spoke or read addresses of congratulation and the meeting was closed by a short speech from the Grand Duke Paul. Over forty letters and telegrams were received from Russia and abroad.

THE EXHIBITION.

A very striking and instructive collection of objects has been brought together and is now open free to the public in the rooms of the Medical Department. Not only is it interesting from a scientific point of view, but the opportunity has not been lost of turning to good account the educational influence of such an exhibition. A number of large diagrams, tables, and maps have been prepared on such a scale that he who runs may read, showing the great influence which the introduction of vaccination has had in diminishing small-pox prevalence. These are hung round the walls of the first room of the exhibition, and in this room are also hung two large pictures; one is a drawing of the Jenner Monument in Boulogne, contributed by the Paris Académie de Médecine. The other is a replica in oils of a picture by an American artist which was exhibited a few years ago on the other side of the Atlantic. It represents Jenner in the act of vaccinating James Phipps—making, in fact, his first successful experiment in vaccination. The scene represented is the garden of Jenner's house; Jenner is seated and holds the boy between his knees, while he inserts the lymph into his arm; and a number of people, gentle and simple, are looking on at the novel procedure, some expressing merely curiosity, while others appear to regard it with anything but approval. In this same room are some interesting historical documents connected with the story of small-pox prevention in the past. Here is the original *gramota* or document signed by the Empress Catherine, conferring nobility on the boy Ospennui, from whom the lymph had been taken for inoculating the Empress in 1768. The famous English medical man, Dr. Dimsdale, it will be remembered, performed this little operation, for which he received the most liberal rewards. The real name of the boy from whom the small-pox lymph was taken was Peter Basof, but Catherine re-named him Ospennui (from *ospa*, small-pox) and raised him to the ranks of the nobility. A somewhat parallel circumstance happened when vaccination was introduced into Russia at the beginning of this century. The Empress Marie, consort of the Emperor Paul, one of the most beneficent and charitable of all Russian empresses, corresponded with Jenner and received direct from him some points or tubes of lymph. These she sent to the great Foundling Hospital in Moscow. The first child to be inoculated was a boy named Anton Petrof, but by command of Her Majesty his name was changed to Anton Vaccinof in memory of the event. Unfortunately, all documents relating to this boy were destroyed or lost during the occupation of Moscow by the French in 1812. Some other papers relating to Ospennui, the vaccinifer of Catherine's time, are shown in the present exhibition.

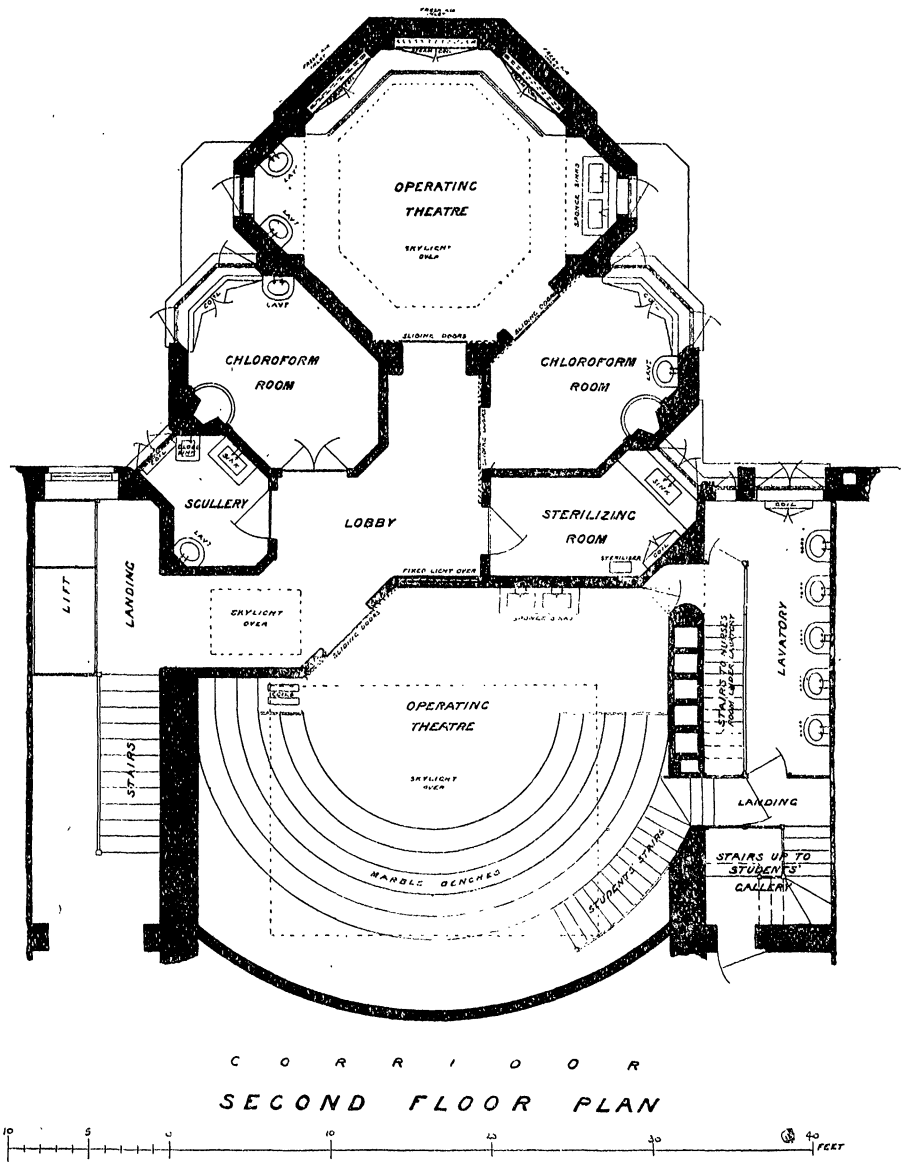
Among the exhibits are contributions from almost every civilised country, including such distant lands as Japan and Brazil. It is impossible here to mention more than a small fraction of these. They are mostly books, reports, tables, diagrams, prints and caricatures, and instruments. The engraved portrait of Lady Mary Wortley Montagu, sent to the society by our own gracious Queen, naturally occupies a prominent position. Here, also, is a very beautiful little gold and enamel casket, which, according to an inscription it bears, was presented to Jenner by the corporation of the City of London in 1803. This is lent by the Society of Apothecaries of London; it is thought to have been presented at the same time that the Freedom of the City was conferred on Jenner, but it is too small to have contained anything in the nature of a document. It has recently been used as a snuff-box.

There is an interesting little collection of medals and plaster casts from medals. One was struck on the death of Peter II., who died from small-pox in 1730; another commemorates the inoculation of the Empress Catherine; others have been awarded at different times to different people who have been zealous in spreading vaccination. One curious object is a Government "Instruction" of last century, a document instructing people in the value of small-pox inoculation and the method of performing it. It is illustrated by two quaint pictures: the one represents a group of wretched-looking peasants bearing a coffin to the cemetery, and underneath it are the words (in Russian): "Terrible results of small-pox: deformity, disease, short life, death." The other shows in contrast a happy village where inoculation has been practised; the peasants and children are dancing to the twanging of a *balalaika*, and underneath is written: "The salutary results of inoculation: beauty, health, long life!"

In the second room is a collection of portraits of Jenner, varying in size from large prints after Northcote, Lawrence, and others, down to a silhouette, miniature size. Opinions will probably always differ as to which is the best likeness of Jenner. The portrait by Sir Thomas Lawrence, of which some good prints are shown, though by the greater artist, is perhaps less satisfactory than some others. Probably the best-known portrait—and not improbably the best likeness—is that after a coloured print by J. R. Smith, in which Jenner is shown leaning with his right arm on the bough of a tree and showing a cow in a meadow in the background. Here, also, are several portraits of contemporaries, supporters and opposers, of Jenner. A number of caricatures from different countries are instructive evidence of the absurd views and fears to which vaccination, when it was first introduced, gave rise.

On a series of shelves placed round this room is a large collection of small-pox literature. Books, pamphlets, and reports in every language and of every size are here displayed. The collection of English authorities appears to be very complete. All Jenner's works (some in the original edition) are here, and among others are such works as those of Moore, Ring, Willan, Bryce, Aikin, Monro, and Kirkpatrick for the early period, and Ceely, McVail, Seaton, Crookshank, and a host of others for more modern times. Among the reports are several drawn up by the Medical Officer of the Local Government Board, presented by him to the Russian National Health Society, and the reports of the special committee of the Epidemiological Society which were laid before the House of Commons in 1851 and 1854 and led to the passing of our present vaccination laws. These are specially bound in Russian leather and bear an inscription on the cover to the effect that they were presented by the Epidemiological Society to the Russian National Health Society on the occasion of the centenary of Jenner's discovery.

Another room of the exhibition contains objects displayed by firms or individuals. There are models of laboratories and of vaccination institutions, apparatus for disinfection, various instruments used in vaccinating animals and human beings, and different forms of tubes or points for preserving lymph. On the walls are tables showing the varying degrees of receptivity to vaccination in various birds and animals. In the centre of this room is a circular stall in which are placed two calves. These calves have been inoculated. They are swathed in large white stable-cloths and attract a considerable amount of attention.



One of the best exhibits in the whole collection is a series of wax models showing the normal development of the vaccine vesicle in a healthy arm and its development in certain morbid conditions. Another series shows the same thing in the calf. They are admirable reproductions. The same praise may be given to a number of large water-colour drawings of small-pox and vaccine vesicles and to others showing their microscopic appearances. The anatomical characters of vaccination are also fully illustrated by a series of photographs and by a number of prints, plain and coloured, gathered from the works of all the best known authorities on the subject.

THE NEW OPERATING THEATRE AT ST. GEORGE'S HOSPITAL.

THE operative surgical work at St. George's Hospital having increased so much as to outgrow the theatre accommodation it was wisely resolved to remodel the old theatre and, at the same time, to build a new one in addition. This undertaking was completed about three months ago, and the formal opening of these new rooms by His Royal Highness the Duke of Cambridge, which took place on Dec. 23rd, 1896, was duly mentioned in THE LANCET of Dec. 26th. As shown in the accompanying illustration, this important department—as now improved, enlarged, and extended—consists of the large (east) theatre which has been completely remodelled, the small (west) theatre which is entirely new, two chloroform rooms (one in connexion with each theatre), a sterilising room, a scullery, a lavatory, and a store-room, and a nurses' sitting-room situated beneath the lavatory. The whole of these rooms are situated, as in the case of the old theatre, about seven feet above the level of the second floor of the hospital, The main approach from the second-floor corridor is by a teak staircase four feet wide; there is also communication between the same corridor and the theatres by means of a patients' lift, an arrangement which does away with the necessity of carrying patients up or downstairs in bringing them to or from the central wards of the second floor—i.e., the Harris and the Wright, Cholmondeley and Radcliffe—from the central wards of the first floor, and from any of the ground-floor wards.

The walls and ceilings of these rooms are entirely lined with glazed tiles, those of the ceilings being separately screwed up, and each tile being made with a lap joint. In the two theatres and the chloroform rooms the lower tiles are of an olive green colour and form a dado of about four feet high. A skirting of the same coloured tiles about eighteen inches high is continued round the corridors, in the scullery, and the sterilising room. The remainder of the tiling of the walls is of a warm cream colour, the ceilings being white. All the corners throughout are rounded, so as to facilitate cleaning, and the whole of the theatres might be washed down with a fire hose. The floors throughout are of marble mosaic, without a central gully. The benches for spectators in the large theatre and the single row in the small theatre are of white marble. The standards and rails in the large theatre are the same that were formerly in use, but in the small one they are of gun-metal tubing. The skylight of the small theatre is constructed entirely of iron, and with the object of equalising the temperature it is double glazed, the space between the two layers of glass being four and a half inches. The daylight illumination of both theatres is very good. The

heating apparatus for the new (or west) theatre consists of three sets of copper pipe coils, containing forty superficial feet and supplied with steam direct from the hospital boilers. The air-supply is filtered through wet screens and warmed by passing over the coils before it is delivered into the theatre. An extraction shaft carried up from the highest part of the theatre discharges at a level above all the surrounding roofs, by which arrangement it is estimated that the whole of the air can be changed once in every six minutes. In the east theatre the old coils are in use. The artificial lighting is entirely by electricity, but gas is laid on in the sterilising-room, where there is a gas-heater fitted to a Schimmelbusch steriliser. Separate electric mains are carried into the east theatre, and can be used for a motor, for electrolysis, the cautery, &c. The instrument cases are made of plate-glass and brass. In order to prevent dust being carried into these cases by the current of air produced when their doors are opened they have ventilation apertures provided with cotton-wool screens which filter the air and arrest the dust; the small hardwood cupboards in which the mackintoshes, porringers, and such like are kept are fitted with ventilation openings on the same principle.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY meeting of the Council was held on Jan. 14th, the President, Sir WILLIAM MACCORMAC, being in the chair.

It was resolved to send a letter to Sir Joseph Lister on behalf of the Council and of the Fellows congratulating him on his elevation to the Peerage.

A report was received from the Dental Section of the Board of Examiners in Dental Surgery in which they recommend a synopsis for the examination in dental metallurgy, and also that the examination in this subject should be conducted by written paper only. The report was approved. The synopsis is given below.

The senior Vice-President reported the proceedings at the half-yearly meeting of Fellows on Jan. 7th, and stated that thirty-nine Fellows were present, including thirteen members of Council.

The thanks of the Council were accorded to Sir Joseph Lister, Bart., F.R.S., for representing the College at the Pasteur Memorial Ceremony on Dec. 26th, 1896. A letter was read from Mr. Howard Marsh, stating that, in anticipation of the expiration on April 8th next of his period of office on the Court of Examiners, he desired to place his resignation in the hands of the Council, to take effect from the end of the Pass examination for the Membership to be held in January. The resignation was accepted, and the President stated that the vacancy thus occasioned, and also the vacancy due to the expiration of Mr. Howse's period of office, would be filled up at the ordinary meeting of the Council on March 11th.

Mr. LANGTON moved: "That it is desirable that no one who has served six years as a representative of this College on the Committee of Management or the Laboratories' Committee shall, on his retirement in rotation from office, be eligible for immediate re-election."—The motion was carried.

SYNOPSIS OF THE EXAMINATION IN DENTAL METALLURGY.

The physical properties of the metals—gold, platinum, palladium, silver, tin, antimony, mercury, lead, bismuth, zinc, cadmium, copper, aluminium, iron, nickel—viz., lustre, tenacity, elasticity, malleability, ductility, conductivity for heat and for electricity, fusibility, specific gravity, specific heat, expansion by heat, brittleness, hardness, crystalline character, change of volume on solidification. Action of air (either hot or cold), of water, of acids, of alkalies and of sulphuretted hydrogen on the above metals and their principal alloys and amalgams. Effect of exposure of the above metals, their alloys and amalgams, in the mouth.

Gold.—Preparation and properties of pure gold. Cohesive and non-cohesive gold. Precipitated and spongy gold. Assay of gold. Calculation of amount of base metal to be added to reduce the fineness of gold to a given carat, or of the amount of fine gold or of gold of high carat needed to be added to raise the fineness of an alloy to a given carat. The detection and estimation of gold in alloys. The purple of Cassius. The effect of impurities on the properties of gold. The properties of the alloys of gold. Composition of solders for gold.

Platinum.—Preparation and properties of platinum. Platinum-black and spongy platinum. Detection and estimation of platinum in alloys. Alloys of platinum with iridium, gold, silver, and other metals. Dental alloy.

Palladium.—Preparation and properties of palladium and its combinations with silver, gold, and mercury.

Silver.—Preparation and properties of pure silver. Assay of silver by cupellation and in the wet way. Preparation and properties of the combinations of silver with copper, gold, platinum, and mercury. Composition and preparation of solders for silver. Electroplating.

Tin.—Preparation and properties of tin. Detection of tin in alloys. Preparation and properties of the alloys of tin. Its combinations with zinc, copper, and mercury. Composition and melting-points of readily fusible alloys.

Antimony.—Preparation and properties. Properties of alloys.

Mercury.—Preparation and properties of pure mercury. Testing the purity of mercury. Vermilion and detection of impurities therein. Preparation and properties of amalgams of the various metals mentioned in this synopsis. Composition and preparation of the principal alloys which have been used for preparing dental amalgams. Methods of testing such amalgams, as to the causes of their change of volume, permanence in the mouth, and change of colour. Effects of different metals in these amalgams. Possible action of amalgam fillings on other metals used in the mouth.

Lead.—Preparation and properties. Effect of alloying on its properties. Solders and soft soldering.

Bismuth.—Preparation and properties. Alloys.

Zinc.—Preparation, purification, and properties. Preparation of zinc oxide, zinc chloride, and the various materials for the oxychloride, oxyphosphate, and oxysulphate cements. Action of acids and alkaline solutions on cements in the mouth. Alloys of zinc.

Cadmium.—Properties, its advantages and disadvantages in alloys and amalgams.

Copper.—Preparation and properties. Effects of impurities on its properties. Alloys. Modes of preparation and properties of copper amalgams. Preparation of Sullivan's amalgam and its modifications.

Aluminium.—Preparation and properties of aluminium and aluminium-bronze. Solders for aluminium and aluminium-bronze.

Nickel.—Preparation and properties. Alloys. German silver. Nickel-plating.

Iron.—Differences between cast iron, wrought iron, and steel. Effect of presence of impurities in iron. Hardening, tempering, annealing, and burning steel.

Methods of testing metals and alloys for their various properties as described in first paragraph.

Methods of testing dental amalgams for changes of volume. Effect of sulphuretted hydrogen, water, air, acids, and alkalies on dental amalgams.

Methods of parting gold from silver; rough tests for fineness of gold alloys (touchstone); of preparation of gold alloy of required fineness; of recovery of gold from scraps; of preparation of solders for gold; of recovery of platinum and silver from scraps; of preparation of pure silver; of preparation of amalgam alloys containing two or more of the following metals—silver, tin, gold, platinum, copper, zinc; of preparation of readily fusible alloys, containing two or more of the metals—tin, lead, bismuth, mercury, cadmium, antimony, and zinc.

Methods of determining melting-points of readily fusible alloys; of preparation of alloys recommended for dies and counter-dies.

Description of furnaces and muffles used in metallurgy.

The blow-pipe; theory and varieties of fluxes.

Colouring and gilding gold.

Purification of sweep or lemel.

THE OUTBREAK OF CHOLERA ON BOARD THE "NUBIA."

BEFORE the outbreak of cholera on board the *Nubia* is altogether relegated to the things of the past and swept out of sight by the stream of succeeding events it seems to us that, in the interest of scientific medicine, it would be as well to inquire a little more closely than has been done into the facts making up the medical history of that outbreak. In the full and lengthy description that appeared in the daily journals there was, so far as we recollect, one important point omitted — namely, the precise date of the vessel's arrival at Colombo. We know from the published account that appeared in our columns last week that it was Dec. 17th, and we also know by a brief paragraph that appeared in the *Indian Medical Record* of Dec. 16th last that "cholera has broken out at Colombo." This information was corroborated by a communication published in the *Times* of the 12th inst., as well as by information we have received from another source; in fact, up to Dec. 22nd, according to papers received from Colombo, there had been 73 fatal cases of cholera in the crowded native quarters at that station.

As regards the way in which the outbreak was dealt with on the arrival of the *Nubia* at Plymouth there is nothing to be said except praise. The measures adopted were those of isolation and observation *not* of quarantine; they were quite wise and reasonable, and, what is more, their adequacy and efficacy have now been ratified by a fair amount of experience, and the local arrangements made for

Hosted by Google

applying such measures were promptly and admirably carried out. With respect to the origin and causes of the outbreak on the *Nubia* a good deal of doubt has been expressed, and the view that the source of the cholera was first contracted at Port Said seems to be regarded as the most probable explanation. But is this so? Do not the facts, on the other hand, point to Colombo? In the first place, it is strenuously denied that there was at the time, or had been recently, any cholera at Port Said or in Egypt. If this be so, it is not easy to understand how a disease or anything else can be communicated which neither the place nor the people had to communicate! Moreover, was the fruit consumed exclusively by the troops on board the *Nubia* or by those first attacked? But the period of incubation, it is alleged, fits in with the assumption that the source of the cholera was Egypt and not Colombo. We will touch upon this point subsequently. That cholera existed at Colombo at the time the *Nubia* was at that port may be taken as a fact; that she there embarked a number of troops of the North Lancashire Regiment—and possibly other soldiers—is also a fact; and, still more interesting, the disease seems to have originated among the men of the North Lancashire Regiment and to have been confined to the military on board; in other words, on the assumption that they carried cholera on board with them they seem to have kept it. The date of the first fatal case actually ascribed to cholera is given as Jan. 2nd—a long interval; but it does not at all follow that some of the baggage, stores, or clothing shipped with the troops at Colombo may not have been opened and exposed subsequently to the departure of the *Nubia* from that port. Be this as it may, however—and we only put it forward hypothetically—the occurrence of cholera in vessels leaving cholera-infected ports at dates beyond the recognised and usually short period of incubation of this disease is not by any means an unknown phenomenon. On the contrary, it would not be at all difficult to adduce instances of the kind from the published records of outbreaks of cholera on ships—of the occurrence, for example, of the first fatal case of cholera from the seventh to the sixteenth day of the voyage and even after the twentieth day. To take the well-known case of the *Renown*. Cholera appeared in Gibraltar on Aug. 19th, 1865. On the 21st the headquarter wing of the 19th Regiment went on board that ship. On the 22nd—the third day after the first fatal case of cholera in Gibraltar—a fatal case occurred on the ship. The vessel was hauled out into the bay and retained there for thirty hours; and, no subsequent case having occurred, she proceeded on her voyage to the Cape. On Sept. 5th following, a fortnight after the fatal case at Gibraltar, there was an outbreak of cholera on board the *Renown* which lasted fourteen days, and the period of this outbreak is stated to have corresponded to that of the maximum intensity of the epidemic in Gibraltar. The left wing of the same regiment, which departed from Gibraltar in another vessel on the very day cholera broke out at Gibraltar, altogether escaped the disease. In the case of the ship *Gertrude* again the facts are interesting. On May 21st, 1859, when a severe epidemic of cholera was prevailing at Calcutta, a number of sick and wounded men were embarked for passage to England. On June 15th following—twenty-four days after all communication with land had ceased—the first fatal case occurred, and the outbreak lasted until June 25th—ten days. In the literature that exists on this subject it has been occasionally observed that the crews, troops, and others, if drawn from separate sources and shipped immediately before sailing, showed no community of attack, cholera being confined to those shipped from a definite quarter.

To return to the *Nubia*. It appears that the origin of the outbreak cannot in this particular case be ascribed to the contamination of the water-supply; that vehicle of the disease was thoroughly investigated and eliminated as a cause because it was found to be inconsistent with the facts of the outbreak. No one can have any doubt, least of all readers of THE LANCET, of the great importance that is attached to the view that cholera is a water-borne disease, but that is very different from saying that it is exclusively so or that the poison must invariably be swallowed, with its consequent corollary and obvious moral that the only safeguard is—the kettle!

We do not pretend, of course, to say that the origin of the outbreak on board the *Nubia* is demonstrably attributable to the cause having been embarked at Colombo, but we do say that all the facts require to be ascertained and most carefully weighed before the correctness of that view be discarded, for, so far as we know them at present, and so far as the medical history of the outbreak goes, there seems to be a good deal to be said in favour of it. Where an opinion has to be based on the facts or on assumptions we prefer to range ourselves for the time being on the side of the facts so far as we know them.

CONGRATULATIONS TO LORD LISTER.

WE have received the following letters for publication from the Registrar of the Royal College of Surgeons in Ireland:—

Royal College of Surgeons in Ireland, Jan. 9th, 1897.

MY LORD,—The Council of the Royal College of Surgeons in Ireland have requested me to tender to you on their behalf and my own our earnest congratulations on your elevation to the peerage. We are glad to recognise that on the first occasion on which such an honour has been conferred upon a member of our profession the recipient should be one who has created a new era in surgery and who has thereby saved innumerable lives. There is no place in which your precepts and practice have been more zealously followed than in this country, and we, in common with all other peoples, are your debtors. We rejoice in the honour which has been conferred upon you by Her Majesty, and we trust that you may live long to exercise that influence upon the practice of scientific surgery which has made your name famous.

I am, My Lord, yours faithfully,
W. THOMSON, President.

[REPLY.]

12, Park-crescent, Portland-place,
Jan. 12th, 1897.

MY DEAR MR. THOMSON,—I esteem it a very high honour to receive congratulation from the body which represents my Irish colleagues in surgery, and I feel it to be enhanced by the circumstance that the gratifying message has been communicated to me by yourself, the President of the College.

I well remember the kind part you took in reporting a small address that I gave many years ago in the Richmond Hospital, an act on your part which, I suspect, had no small share in diffusing among your Irish brethren the principles of antiseptic surgery. I beg you to express to your colleagues on the Council the great gratification which they have caused to me, and

Believe me, very sincerely yours,
JOSEPH LISTER.

THE LONDON WATER QUESTION.

AT the meeting of the Society of Chemical Industry on Monday last an important paper on "The Character of the London Water Supply" was read by Mr. W. T. Dibdin, the chemist to the London County Council. The speaker first called attention to a point that has been largely overlooked—viz., the character of the matters held in suspension in presumably pure waters. Although small in quantity these materials were often of such a kind as to throw considerable light on the source and quality of the water in a way that the old methods of analysis failed to do. For a considerable period daily analyses had been made of the water supplied to London by the different companies and of the water of the river Thames at the intakes of the companies deriving their supply from that source. After several improvements in the method of examination a specially constructed micro-filter was at length employed, enabling the quantity of suspended matter to be stated volumetrically as millimetres per litre. A further advantage of this method was that the deposit could be used afterwards for microscopical examination. The quantities of suspended matters present in the Kent, West Middlesex, and New River waters during 1895 were practically the same—0·0011 grain per gallon—and Mr. Dibdin accepted this proportion as the unavoidable minimum due to "rust and dust." The average quantities present in the other London supplies, however, amounted to 0·0033 grain per gallon, leaving 0·0022 grain of avoidable suspended matter. If the West Middlesex was capable of so purifying Thames water as to reduce it to the high standard of the Kent and New River waters there was no reason why the other companies drawing their supplies from the Thames should not do the same. The average quantities of suspended matter in the various waters

Hosted by Google

determined on the micro-filter and gravimetrically were as follows:—

Company.	Mm. in micro-filter per litre of water.	=	Grains per gallon.
Kent	0·3	=	0·0007
New River	0·3	=	0·0010
West Middlesex	0·4	=	0·0009
Chelsea	0·4	=	0·0021
East London	0·6	=	0·0025
Grand Junction	0·4	=	0·0023
Lambeth	0·4	=	0·0021
Southwark	0·7	=	0·0039
River Thames at Sunbury ...	12·0	=	0·7569

This table showed that the deposit from the Grand Junction, Southwark, Lambeth, and Chelsea waters was of a much higher specific gravity than that from the Kent, New River, and West Middlesex waters, the large quantities of débris and decaying organic matter present in the former accounting for the difference. Taking the whole into consideration Mr. Dibdin was of opinion that in the case of a water containing less than 1 mm. per litre (using a micro-filter tube of 2 mm. diameter), equal to 0·004 grain per gallon, no notice need be taken of the deposit unless the microscopical examination showed the presence of objectionable matter. The estimation of the percentage of nitrogen in the volatile organic matter brought out strong differences between the waters derived from the Thames—with the exception of the West Middlesex—and the other London waters, as will be seen from the following table:—

Chalk ...	Kent...	...	...	2·12
	Southwark ...	3·44		
	Lambeth ...	3·42		
	Chelsea ...	2·97	...	3·27
	Grand Junction ...	3·66		
	West Middlesex ...	2·86		
New River...	New River	...	...	2·86
Lee... ...	East London	...	...	2·97
Thames Intakes (Sunbury)	... ...	...	...	4·06

A diagram showed clearly that the nature of the deposit from Thames water, judged from this standpoint, closely resembled that from raw Thames water and even polluted river mud. The microscopical examination of the waters showed that 30 per cent. of those derived from the Thames should be classed as objectionable—i.e., containing large quantities of débris infested with bacteria, paramecia, and other infusoria. The quantity of bacteria seemed to be in close relation to the quantity of organic débris, and the discrepancies found between the results of different observers may be due to the variation in the quantity of débris included. The average number of bacteria present, determined by cultivation on gelatin plates, varied from 90 per c.c. in the Kent water to 352 in the Southwark. The Lambeth water gave 294, East London 277, and Grand Junction 170, the others being comparatively low. These results were compared with the figures obtained in 1891-92, when the Kent water gave 4795, Southwark 4594, Lambeth 4626, East London 3387, and the others between 2000 and 3000. Mr. Dibdin ascribed this improvement to the influence on the companies of the evidence given before the Royal Commission.

An interesting comparison was made between the present London supply and the Welsh mountain streams, unfiltered. With the exception of the Kent water the difference between them did not seem to be very marked. Lovibond's tintometer, however, whilst showing no yellow tint in the Kent water and practically none in the Welsh, registered a considerable proportion in the London supply. Mr. Dibdin concluded his paper with a few facts relating to the possibilities and advantages of purifying London water by softening with lime.

In the subsequent discussion, which had to be adjourned owing to the lateness of the hour, Dr. Frankland's assistant, Mr. BURGESS, said that he had a close acquaintance with the analysis of London waters. He did not agree with many of Mr. Dibdin's results, especially his figures for organic nitrogen, which he considered too high. He had had no personal experience with a micro-filter, but suggested that the high figures obtained by Mr. Dibdin for organic suspended matter might be due to the length of main through which some of the water had travelled. Especially he thought this might be the case with the Southwark water. He pointed out that, owing to floods, the year 1891-92 was a very bad one for the water companies, and he disputed Mr. Dibdin's inference that the subsequent improvement was due to the evidence before the Royal Commission.

Dr. DUPRÉ said that, in his opinion, water known to be contaminated should be rejected entirely for domestic purposes. He thought that the principal danger to London lay in the possibility of an epidemic occurring among the population higher up the river. Instancing the cholera epidemic at Hamburg, Dr. Dupré said that the Hamburg people had drunk the water of the Elbe for many years with impunity, but the cholera infection coming down with the river water had caught the city undefended. Altona—a suburb of Hamburg—it was thought was secure on account of its filter-beds, but on one occasion the filter-beds broke down, and the number of deaths that occurred would have been equivalent to 5000 in the London water area. Dr. Dupré said that Professor Koch declared that water containing over 100 bacteria per cubic centimetre should be run to waste, and that if it exceeded this limit, the population should be warned. This, however, was practically useless, as the infection would have two days' start. It would be interesting to compare the statistics of epidemics above the intake with the figures for London itself. Dr. Dupré said that a proper water supply was simply a question of cost. The people of London should be warned, and if they chose to run the risk they should do so with their eyes open.

Mr. FLETCHER pointed out the danger of floods in the Thames. The great advantage of having a Welsh supply would be the security against fæcal contamination of the water supply.

Mr. WM. THORP asked questions about the method of collection and disagreed with Mr. Dibdin's method of recording the amount of the deposit on the micro-filter.

Dr. VOELCKER said that the micro-filter failed to distinguish between quality and quantity, and he thought that the fine earthy material brought down when the river was in flood would interfere with deductions based upon it. He did not consider that the harmony between the quantity of mud and the quantity of bacteria had been established. He thought that too much was made of the presence of bacteria. Until it was known which bacteria were good and which were harmful it was unwise to draw conclusions from the presence of bacteria. The London water was infinitely better than most of the country supplies and he thought that the bad condition of cisterns and pipes inside the houses was far more dangerous to health than the small quantity of impurity that escaped the filter-beds of the companies.

After a few remarks from Mr. NEWLANDS the meeting adjourned.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Enteric Fever at Middlesbrough.—The medical officer of health of Middlesbrough was appointed prior to March, 1880, and hence he is under no legal obligation to submit his annual report to the Local Government Board. The Middlesbrough town council are anxious, it appears, to perpetuate as long as possible this unsatisfactory relation, or, rather, want of relation, with the central health authority. Some of the councillors have, they say, a holy horror of "red tape," while others seem to prefer to keep both their insanitation and their enteric fever to themselves. Unfortunately in the matter of enteric fever this is more easily said than done, and doubtless Middlesbrough has, in some instances at least, been instrumental in conveying the disease outside its own territory. Indeed, the prevalence of enteric fever has of late been so marked in Middlesbrough that the Local Government Board recently decided to ascertain, through one of their own officers, the actual condition of affairs. As the result of this decision Dr. Bruce Low has written an elaborate report upon the subject. From the latter we learn that Middlesbrough, which is built on a flat, low-lying ground contiguous to the Tees, and has a population of some 86,000, has for years been unduly afflicted with enteric fever; in fact, the disease is

Hosted by Google

endemic there, and instead of diminishing shows signs of increasing. Dr. Bruce Low deals only with such figures as relate to the five years embraced between July 1st, 1891, and June 30th, 1896. Prior to the first of these two dates there were two notable outbursts of enteric fever in the Tees valley, and Middlesbrough was one of the districts involved. These outbursts, which were sudden and transient in character, were traced by Dr. Barry to the fouling of the Tees water above the intake of the water company which supplied the districts affected. In the present instance Dr. Bruce Low found that although all the ten wards of the borough were invaded four of them showed an exceptional incidence of the disease throughout the period to which the report relates, and in a characteristically lucid fashion Dr. Low discusses how far the causes which are usually held to account for the prevalence of enteric fever have been operative. He dismisses milk and water as failing to account for the prevalence of the disease, there having been no sudden outburst such as was observed in 1890 and 1891 by Dr. Barry, and further, the chief prevalence of the disease has been in wards where exceptionally insanitary conditions obtain; it has, too, to be noted that but little Tees water is now used and that very shortly even this will be discontinued. There have, Dr. Low thinks, been operative in Middlesbrough two agencies which may be held in large part to account for the endemic incidence of enteric fever in certain localities, these agencies being defective privies and sewers. In respect of the former it is to be narrated that situated as they are above the ground level their contents tend to leak out and to foul the superficial layers of the soil and to thus pollute the atmosphere. The sewers in the chiefly invaded districts are defective and inadequate, and during periods of high spring tides and heavy rainfall the sewage is dammed back into the sewers and at times escapes into cellars and yards. The association between the midden privies and ashpits and enteric fever is seen by the accompanying table:—

Table XI., showing the Number of Houses served by Pan Closets, by Midden Privies, and by Waterclosets in Middlesbrough in 1896, with the Incidence of Enteric Fever Cases on Houses served by one or other Method during the last Five Years.

—	Total number.	Enteric fever attacks in houses of each class during the last five years.	Enteric fever attacks per cent. of houses in each instance.
Houses served by ashpans	8,502	603	7·09
Houses served by midden privies	3,274	320	9·77
Houses served by waterclosets ...	1,296	21	1·62
Total	13,072	944	7·22

We have not space to notice more fully Dr. Low's carefully arranged report, but we must endorse its concluding sentences, and express a hope that the town council of Middlesbrough will not refuse to be guided by their own skilled advisers and that the sewers will be re-constructed and the remaining 3000 privy middens be abolished forthwith.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 7127 births and 4055 deaths were registered during the week ending Jan. 16th. The annual rate of mortality in these towns, which had been 22·3 and 19·4 per 1000 in the two preceding weeks, further declined last week to 19·2. In London the rate was 18·0 per 1000, while it averaged 20·1 in the thirty-two provincial towns. The lowest rates in these towns were 9·1 in West Ham, 15·4 in Portsmouth, 15·5 in Brighton, and 15·9 in Leicester; the highest rates were 23·9 in Wolverhampton, 24·9 in Preston, 25·1 in Liverpool, and 28·3 in Plymouth The 4055 deaths included 378 which were referred to the principal zymotic diseases, against 436 and 415 in the two preceding weeks; of these, 90 resulted from whooping-cough, 77 from diphtheria, 73 from measles, 49 from diarrhœa, 45 from "fever" (principally enteric), and 44 from scarlet fever. No death from any of these diseases occurred last week in Norwich or in Bolton; in the other towns they caused the lowest death-rates in Croydon, Brighton, Burnley, and Birkenhead, and the highest rates in Birmingham, Manchester, Bristol, Blackburn, and Nottingham. The greatest mortality from measles occurred in West Ham, Portsmouth, Plymouth, Nottingham, and Bradford; from scarlet fever in Gateshead; from whooping-cough in Bristol, Nottingham, Blackburn, Huddersfield, and Sunderland; and from "fever" in Halifax. The 77 deaths from diphtheria included 52 in London, 9 in Birmingham, 3 in Bristol, 2 in Liverpool, and 2 in Leeds. No fatal case of small-pox was registered during the week under notice, either in London or in any other of the thirty-three large towns. There were 3 cases of small-pox under treatment in the Metropolitan Asylum Hospitals on Saturday last, the 16th inst., against 3 and 2 at the end of the two preceding weeks; 1 new case was admitted during the week. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital was 3414, against 3763, 3707, and 3597 on the three preceding Saturdays; 208 new cases were admitted during the week, against 219, 271, and 290 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 348 and 335 in the two preceding weeks, further declined to 306 last week, and were 495 below the corrected average. The causes of 57, or 1·4 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Cardiff, Bradford, and in eight other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Birkenhead, Liverpool, and Preston.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased in the seven preceding weeks from 20·3 to 22·8 per 1000, declined to 21·9 during the week ending Jan. 16th, but was 2·7 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 17·3 in Aberdeen and 18·0 in Leith to 23·5 in Glasgow and 23·8 in Paisley. The 654 deaths in these towns included 28 which were referred to measles, 26 to whooping-cough, 11 to diarrhœa, 4 to "fever," 3 to scarlet fever, and 3 to diphtheria. In all, 75 deaths resulted from the principal zymotic diseases, against 103 and 101 in the two preceding weeks. These 75 deaths were equal to an annual rate of 2·5 per 1000, which exceeded by 0·7 the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 48, 60, and 45 in the three preceding weeks, further declined to 28 last week, of which 25 occurred in Glasgow. The deaths from whooping-cough, which had been 15 and 20 in the three preceding weeks, further rose to 26 last week, of which 23 were recorded in Glasgow and 2 in Edinburgh. The 4 deaths referred to different forms of "fever," showed a decline of 2 from the number in the preceding week, and included 3 in Glasgow. The fatal cases of scarlet fever, which had been 10, 5, and 10 in the three preceding weeks, declined to 3 last week. The 3 deaths from diphtheria corresponded with the number in the preceding week, and included 2 in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 151 and 152 in the two preceding weeks, further rose to 162 last week, and exceeded by 31 the number in the corresponding week of last year. The causes of 34, or more than 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 44·1 and 35·2 per 1000 in the two preceding weeks, further declined to 34·8 during the week ending Jan. 16th. During the last quarter the death-rate in the city averaged 27·6 per 1000, the rate during the same period being 18·1 in London and 17·8 in Edinburgh. The 233 deaths registered in Dublin during

Hosted by Google

the week under notice were within 3 of the number in the preceding week, and included 47 which were referred to the principal zymotic diseases, against 36 and 40 in the two preceding weeks; of these, 27 resulted from whooping-cough, 9 from measles, 5 from scarlet fever, 4 from "fever," 2 from diarrhœa, and not one either from small-pox or diphtheria. These 233 deaths were equal to an annual rate of 7·0 per 1000, the zymotic death-rate during the same period being 1·7 in London and 1·2 in Edinburgh. The fatal cases of whooping-cough, which had been 15, 23, and 19 in the three preceding weeks, rose again to 27 last week. The 9 deaths referred to measles corresponded with the number recorded in the preceding week. The fatal cases of scarlet fever, which had been 1 and 4 in the two preceding weeks, further rose to 5 last week. The 4 deaths referred to different forms of "fever" were within one of the number in the preceding week. The 233 deaths in Dublin last week included 40 of infants under one year of age and 48 of persons aged upwards of sixty years; the deaths of infants showed an increase, while those of elderly persons showed a further decline from those recorded in recent weeks. Four inquest cases and 3 deaths from violence were registered; and 68, or nearly a third, of the deaths occurred in public institutions. The causes of 19, or more than 8 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF JAMAICA.

According to the annual report of the Registrar-General of Jamaica for the year ended March 31st, 1896, the total estimated island population at the close of the official year was 694,865, the last census taken in 1891 having shown an enumerated population of 639,491. The marriages during the year numbered 3242, equal to a rate of 4·6 marriages per 1000 of the population; this rate shows a decline on those of the preceding five years. The births registered during the year numbered 26,842, giving a rate of 38·8 births per 1000 of the mean population. Of these births, 16,331 were illegitimate; the general illegitimacy rate is therefore 60·8 per cent. of the total births, but in several localities the proportion was higher than this—in the parish of St. Thomas, for instance, it was 73·7 per cent. The deaths registered in the year numbered 15,716, the rate per 1000 mean population being 22·7. Of the total deaths 4791, or 30·5 per cent., were those of children under one year of age; whilst 6819, or 43·4 per cent., were of children under five years of age. Of the 15,716 deaths in the year 11,688, or 74 3 per cent., were registered without any medical certificate of cause of death being obtained. The following are a few of the more noteworthy items in the tables of causes of death: chicken-pox, 3; measles, 9; influenza, 247; whooping-cough, 326; diphtheria, 16; cerebro-spinal fever, 21; enteric fever, 75; small-pox, 0; scarlet fever, 0; typhus fever, 0; yellow fever, 0; intermittent, remittent, and malarial fever, 383; cancer, 115; phthisis, 1182; lepra, 39; elephantiasis, 8; yaws, 25; sunstroke, 3; and lightning, 3. A great many cases are vaguely described—such as fever (undistinguished), 2489; old age, 1374; convulsions, 1462; and "ill-defined and not specified causes," 2059.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-MAJOR W. F. HEFFERNAN and Surgeon-Lieutenant H. A. L. Howell embark for service in India. Surgeon-Major W. W. Pike has been placed under orders for India.

Surgeon-Major Alexander Sharpe, M.D., retires on retired pay. Surgeon-Major George D. Hunter, D.S.O., from the Seconded List, to be Surgeon-Major, vice W. J. Macnamara, M.D., seconded.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of Surgeon-Captain J. Chaytor-White (Bengal) are placed temporarily at the disposal of the Government of the North-West Provinces and Oudh. The services of Surgeon-Captain J. Davidson, Bengal Establishment, are placed temporarily at the disposal of the Government of the North-Western Provinces and Oudh for employment on famine duty. Surgeon-Captain Narendra Prassanna Sinha, Civil Surgeon of Noakhali, is appointed on return from furlough, to act as Civil Surgeon of Puri until further orders. The services of Surgeon-Lieutenant C. D. Dawes are replaced at the disposal of the Government of India in the Home Department. The undermentioned officers on arrival from England are posted to general duty as follows:—Surgeon-Major Sloggett, to the Nagpore District; Surgeon-Lieutenant Morgan, to the Bombay District; and Surgeon-Lieutenant Dove, to the Bombay District.

NAVAL MEDICAL SERVICE.

The following appointments are notified:—Fleet-Surgeon Michael Fitzgerald to the *St. George*, additional for service in hospital ship *Malacca*. Staff-Surgeons: Alexander G. P. Gipps to the *St. George*, additional; William Eames to Plymouth Hospital; and Henry W. D. Walsh to the *Lion*. Surgeons: John Grant, George M'Gregor, Richard H. Way, and Edward Sutton to the *St. George*, additional, for hospital ship *Malacca*, and Richard A. Fitch to the *Excellent*.

VOLUNTEER CORPS.

Rifle: 1st Volunteer Battalion the Royal Sussex Regiment: Surgeon-Captain C. W. J. Chepmell, M.D., resigns his commission.

RETIREMENT OF BRIGADE-SURGEON-LIEUTENANT-COLONEL E. J. FAIRLAND.

We regret to announce that news has reached us that Brigade-Surgeon-Lieutenant-Colonel Fairland (at present Assistant Professor of Military Medicine at the Army Medical School, Netley and officer in charge of the medical division of the Royal Victoria Hospital) has been obliged, owing to private affairs, to decline the offer of promotion to the rank of Surgeon-Colonel, the acceptance of which would necessitate his going out to India at an early date. We feel that this intelligence will be received with great regret, not only by his departmental brother officers, but also by the officers and men of the army, for Brigade-Surgeon-Lieutenant-Colonel Fairland has ever discharged his duties in a thoroughly conscientious and most able manner, and his kindness of heart, firmness, and courtesy to those of all ranks have deservedly rendered him one of the most popular medical officers of the army. His retirement is a distinct loss to the Service, and it is to be regretted that private affairs have obliged him to send in his papers at a time when his promotion to administrative rank would have opened up a new field of usefulness and activity. Brigade-Surgeon-Lieutenant-Colonel Fairland was gazetted a staff assistant surgeon on April 1st, 1867. He served in the Abyssinian Campaign from September, 1867, to October, 1868, receiving the Abyssinian medal for his services; and in July, 1869, was gazetted assistant surgeon in the 21st Hussars, with which regiment he remained stationed at Umballa and Lucknow till the warrant creating a unified medical department was issued in 1873. In November, 1873, he was appointed staff surgeon at Lucknow by Sir Henry Tombs, V.C., K.C.B, G.O.C., and he held the post until 1880, receiving the thanks of Government for duty during the cholera epidemic and for his successful administration of the lock hospitals. From 1880 to 1882 he served at Pachmari, and subsequently as staff surgeon at Devonport. In May, 1883, he proceeded to Peshawur, where he was in medical charge of the Station Hospital and staff surgeon until the April of 1887. He was afterwards at Pachmari from 1887 to 1889; in medical charge of Dover Castle, and for many months acting Principal Medical Officer of the South-Eastern District during the years 1889, 1890, and 1891, and at Bermuda from April, 1891, until September, 1892, where he was in medical charge of St. George's and for some months senior medical officer. In 1892 the late Director-General summoned him home to fill his present office. When in the year 1879 Brigade-Surgeon-Lieutenant-Colonel Fairland, then a Surgeon-Major, relinquished his post at Lucknow, the Lieutenant-General placed on record by the hand of his Assistant-Adjutant-General his high approval of Surgeon-Major Fairland's work in these terms:—"The Lieutenant-General considers it a duty to express the very high opinion he entertains of your admirable services as staff surgeon. He desires me to say that no one could excel you in your estimate of the requirements of duty, nor could anyone bring to them more earnest attention or greater singleness of purpose. It is his especial privilege to be the mouthpiece of the members of this community, ladies as well as gentlemen, not forgetting the many members of the non-commissioned grade, all of whom look to you for

Hosted by Google

skill and kindness with a confidence which speaks for itself. The Lieutenant-General desires me to particularly dwell upon the devotion with which you daily visit the military prisons. This and the subject of your general discharge of duties are known to His Excellency the Commander-in-Chief." These extracts, although referring to only a few years of Brigade-Surgeon-Lieutenant-Colonel Fairland's work, may be taken as a faithful description, not only of the manner in which he has discharged his duties, but of the esteem in which he has been held ever since he entered the army.

DEATHS IN THE SERVICES.

Deputy Inspector-General Frederic John Mouat, M.D., F.R.C.S., LL.D. (retired), formerly Inspector-General of Prisons, Bengal, and late Inspector, Local Government Board, on Jan. 12th, aged eighty-one years. He was at one time Justice of the Peace for Calcutta, Professor of Chemistry and Materia Medica and Chemical Examiner to the Government, Professor of Medicine and Medical Jurisprudence and First Physician of the Medical College in Calcutta, and Secretary of the Council of Education, Bengal. For two years (from 1890 to 1892) he was President of the Royal Statistical Society, and was a Fellow of the Royal Geographical Society. He was also a Fellow of the Society of Arts, and member of the Faculties of Medicine and Arts of the Senate of Calcutta University. An obituary notice of the deceased officer, who was a valued contributor to the columns of THE LANCET, will be found on page 282.

THE BENIN EXPEDITION.

As we anticipated last week the treacherous conduct of the King of Benin has led to a punitive expedition being ordered to proceed to the West Coast of Africa. Two cruisers, the *Theseus* and *Forte*, have already started, having on board 544 and 318 officers and men respectively. The *Bathurst* has been commissioned for conveying stores. The Oriental Company's steamer *Malacca* has been chartered for service as a hospital ship.

LEAN'S ROYAL NAVY LIST.

The January issue of this up-to-date publication lies before us. It is now too well known to need any description, and we need only remind those who are in any way interested in Naval matters that the new quarterly issue can be obtained from the publishers, Messrs. Witherby and Co., 326, High Holborn, and 4, Newman's-court, Cornhill.

Viscount Wolseley is stated to be recovering from an attack of jaundice. The Commander-in-Chief is expected to be able to resume his post at the Horse Guards almost immediately.

Notification has been received intimating the departure from Bombay on Dec. 24th, 1896, of the transport *Victoria*, with forty-five invalids for the Royal Victoria Hospital, Netley.

LITERARY INTELLIGENCE.—The Rebman Publishing Company, Limited (11, Adam-street, Strand), have ready a small work by Dr. F. W. Forbes Ross on alimentary and digestive derangements in infants and young children entitled "Intestinal Intoxication in Infants."

UNIVERSITY OF CAMBRIDGE.—Dr. James Ward, Fellow and Tutor of Trinity College, and well known for his contributions to psychology, has been appointed to the new chair of Mental Philosophy and Logic. Dr. E. Barclay Smith has been appointed Senior Demonstrator of Anatomy, and Dr. F. C. Kempson, Junior Demonstrator. At the congregation on Jan. 14th the following were admitted to the degrees of M.B. and B.C.: W. Langdon Brown, of St. John's College; A. L. Tatham, of Gonville and Caius College; A. F. Shoyer, of Trinity Hall; and G. A. Auden, of Christ's College. The following took the B.C. degree only: A. G. Butler and C. F. Lillie, of St. John's College; and F. W. H. Hutchinson, of Trinity Hall. Mr. W. Bateson, F.R.S., of St. John's College, is giving this term a series of lectures on the Study of Variation, a subject which he has made peculiarly his own. Dr. Alexander Hill, Master of Downing, will read a paper at the Cambridge Philosophical Society on Jan. 25th on the results he has obtained by staining the brain by the chrome-silver method.

Correspondence.

"Audi alteram partem."

A CENTRAL HOSPITAL BOARD FOR LONDON.

To the Editors of THE LANCET.

SIRS,—I am desired to send you a line in regard to an important meeting which is to be held on Monday next, the 25th inst., at 4.30 P.M., at the Royal United Service Institution. The question under discussion at that meeting will be the desirability of the establishment of a central hospital board for London. How large a measure of support the proposal has already received is indicated by the preliminary list of those who have consented to join the preliminary general committee that may be appointed for its promotion. Judging from this, it would seem that the medical profession in London is now in earnest in its desire to make some very needful reforms in the administration of the medical charities with which they are so closely connected. On points of detail there may be many differences, which can only be met by discussion and concession, but, in spite of these, one or two main propositions appear to receive general acceptance. They may be summed up as follows. That a central hospital board should be established on a representative basis. That in the development of the organisation of medical charity in London reliance should be placed, not on legal measures or compulsion, but on co-operation and publicity. That, with a view to carrying out measures for which there is in some cases urgent need, a central fund should be established in the nature of a permanent endowment for the large and liberal aid of hospitals for special purposes, such as re-building, &c., on lines similar to those already adopted with success by the Charity Commissioners in the establishment of polytechnics in the metropolis. Such a method of aid would not interfere with the voluntary contributions paid to hospitals by the general public year by year.

A further proposal is that, while the body which may be formed should, as representative of the hospitals, settle questions of general policy and discuss reports, &c., a competent executive committee should be created to deal with the various questions of detail that must necessarily arise. Further particulars in regard to the scheme will be found in the accompanying document. The scheme is submitted as a draft, but it is only right to add that it has been scrutinised by many members of the profession, and on various points modified in accordance with their suggestions. At the meeting on Monday a resolution in approval of the plan now suggested as a basis for practical organisation will be moved by Sir William Broadbent, Bart., M.D. Lond., and supported by the following:—Mr. G. D. Pollock, F.R.C.S. Eng., Dr. Lauder Brunton, LL.D., F.R.S., and Mr. Victor Horsley, F.R.S., and a general committee will be appointed. Invitations to the meeting have been sent to medical men throughout London, and I write this line to you in the hope that, in view of the importance of the subject, they may be induced to be present and take part in the meeting, in spite of the many professional engagements that devolve upon them.

I am, Sirs, yours faithfully,

C. S. LOCH, Secretary.

Charity Organisation Society, 15, Buckingham-street, Strand, W.C., Jan. 18th, 1897.

THE TREATMENT OF OMENTAL HERNIA WHEN ACCOMPANIED BY SYMPTOMS OF ABDOMINAL OBSTRUCTION.

To the Editors of THE LANCET.

SIRS,—The recent inquiry into the charge against a member of the staff of the Adelaide Hospital raises a question of considerable surgical interest—viz., the treatment of hernia when symptoms of strangulation are present, but where on opening the sac it is found to contain no intestine, but omentum only. Under these circumstances the symptoms

Hosted by Google

are generally due, not to strangulation of the omentum, but to constriction within the abdomen of some portion of intestine which is bound down by an omental band continuous with the pedicle of the piece of omentum contained within the sac of the hernia. In the interesting editorial article on the case which appears in THE LANCET of Jan. 16th it is pointed out that under these circumstances two courses of treatment are open—viz., (1) to follow up the omentum to the crural ring; or (2) to perform laparotomy; the latter course being recommended as preferable if the patient's condition will admit it. It is my experience that without proceeding to the more serious operation of laparotomy relief will be afforded if—after ligaturing the pedicle and removing the omentum—the pedicle is carefully separated from all adhesions at the neck of the sac and then allowed to slip back into the cavity of the abdomen. In this way, by liberating the omentum, the strangulation of the intestine within the abdomen is at once relieved. This treatment I have found successful in four cases of strangulated (?) femoral omental hernia, one of which I have reported in detail in THE LANCET.[1] In each instance recovery took place, removal of the omentum in the hernial sac and liberation of the pedicle being at once followed by a subsidence of the symptoms of abdominal obstruction. The condition, which apparently is not very uncommon, I have only met with in old irreducible omental herniæ of the femoral variety.

I am, Sirs, yours faithfully,

F. A. SOUTHAM.

Manchester, Jan. 18th, 1897.

"THE GLANDULAR FEVER OF CHILDHOOD."

To the Editors of THE LANCET.

SIRS,—In calling the attention of the profession to the *primâ facie* reasons for regarding glandular fever as a clinical entity Dr. Dawson Williams has, I think, done valuable service. It is largely on the observation and inferences of those engaged in general practice that further definite knowledge of the subject must depend, for the probable communicability and benignity of the disease must tend to exclude it to a great extent from the scope of ward and consulting practice. I am induced at this moment to write these few lines by having lately seen a child suffering from marked anæmia and other symptoms of ill-health whose ailments dated from an attack which, as described to me, seemed in all ascertainable points to tally with the account given by Pfeiffer of glandular fever. Two other children had suffered in the same way; all had had the glands on the neck enlarged and tender, none had had any marked throat trouble, and the affection was regarded as mumps with a difference, there having been apparently no swelling of the face. In the family, the mother, who was quite young, had also suffered slightly, but soon recovered completely. Most of those who see sick children are aware of cases, of no very infrequent occurrence, with fever and some degree of cervical adenitis which are not to be associated with any marked pharyngeal trouble, but are still (owing to glandular fever being, as Dr. Dawson Williams says, ignored) attributed to a hypothetical tonsillitis or other affection that has escaped observation. The examination, in future, of the lymphatic glands of the body generally and of the liver and spleen, in all such cases may go far towards giving us definite and important knowledge on this subject, to the literature of which Dr. Williams has given so interesting and practical a contribution in THE LANCET of Jan. 16th.

I am, Sirs, yours faithfully,

Harley-street, W., Jan. 18th, 1897. H. B. DONKIN.

To the Editors of THE LANCET.

SIRS,—I have read with interest the paper by Dr. Dawson Williams on Glandular Fever in THE LANCET of Jan. 16th. Four years ago, when registrar to the Hospital for Children and Women, Waterloo-bridge-road, three cases of fever of five or six days' duration, in which abdominal pain and very marked constipation were present, led me to think it possible that there might be an undescribed fever of short duration with constipation as a prominent symptom. I subsequently became acquainted with a description of glandular fever, and although I had not noticed any enlargement of lymphatic glands it seemed probable that these three cases were examples of that disease. That conclusion as to their nature may not have been correct, but they drew my attention to the existence of glandular fever, and since that time I have been on the lookout for it. Not, however, until the last week or two have I seen any case that seemed to be an undoubted example. A fortnight ago I was asked to see a girl aged eleven years who only a few weeks ago returned to Clifton from the house of a medical friend in North Ireland, where she had been laid up with a prolonged attack of rheumatism which seriously affected the heart. I found her looking very ill and disinclined to move, the disinclination being largely due to pain in the neck on turning the head. There was swelling in the region of the anterior triangle on either side of the neck, and on palpation the lymphatic glands lying in front of the anterior border of the sterno-mastoid muscle were found to be enlarged and very markedly tender. The lymphatic glands in the posterior triangles were not then examined, but a few days later it was mentioned that the back of the neck was noticed to be tender when the head was laid on a pillow. The glands in these triangles were then found to be enlarged. Those in the axillæ and groins were not affected. There was some difficulty of swallowing owing to a sense of constriction in the throat, but nothing abnormal could be seen. The temperature was raised for five days, reaching to between 102° and 103° in the evening and falling to 101° in the morning. There was obstinate constipation while the temperature remained raised. Two other children, aged nine years and thirteen years, had previously been similarly affected, but to a much slighter degree. Curiously enough, two adults also, between the ages of forty-five and fifty years, had suffered from tender, swollen glands in the neck, but nothing else had attracted their attention. There apparently had been no indication of fever and no difficulty of swallowing. Another case which I consider to be an example of this disease is at present attending the out-patients' department at the Children's Hospital and I intend to ask other medical men if they have noticed similar cases.

I am, Sirs, yours truly,

Clifton, Bristol, Jan. 18th, 1897. THEODORE FISHER.

"LIQUID VACCINE VIRUS."

To the Editors of THE LANCET.

SIRS,—I have seen an annotation under the above heading in THE LANCET of Jan. 2nd, but owing to my absence from England have been unable to take earlier notice of the matter. The statement is made on the authority of your New York Correspondent that, as the result of a series of experiments, the Public Health Department has decided that the best vaccine material is to be obtained by triturating the vesicle pulp with glycerine. This method of preservation is described as *new*, but I think I may justly claim that this is hardly the case, seeing that I demonstrated this means of producing absolutely pure vaccine lymph as long ago as 1891 at the meeting of the International Congress of Hygiene, held in London. On many subsequent occasions also, and especially in my evidence before the Royal Commission on Vaccination,[1] I have had occasion to direct attention to the value from a bacteriological point of view of this method. When properly applied it ensures the destruction of all extraneous microbes, such as those concerned in the various processes of an inflammatory nature which may happen to be present in the contents of the vaccine vesicle at the time of collection. Although this is the case, the addition of glycerine in no way impairs, but rather increases, the specific activity, as vaccine, of the resulting mixture.

I am, Sirs, yours faithfully,

S. MONCKTON COPEMAN.

Savoy Hotel, Berlin, Jan. 9th, 1897.

DR. R. R. RENTOUL AND THE MIDWIVES BILL.

To the Editors of THE LANCET.

SIRS,—The mis-statements and fallacies in Dr. Rentoul's address have most of them been refuted. As some may

[1] A Case of Intestinal Obstruction Relieved by Liberating the Omentum from an Omental Hernia.—THE LANCET, Aug. 14th, 1886.

[1] Final report of Royal Commission on Vaccination, para. 448.

Hosted by Google

still be misled by them, we ask permission to point out a few of the most important. He says: 'Owing to the action of a few practitioners, who contend that the wives of the poorer and wage-paid classes should have no one to help them during their confinements but midwives ....." We know of no one who advocates this. He speaks of a clause which "proposes to hand over all confinements, natural and abnormal, to the sole control of the midwife." There is no such clause. No one ever proposed to do such a thing. "All practical practitioners know that no labour can be definitely defined as 'natural' until some hours or days after the labour is over." Just so. No man can be pronounced healthy till he has been well examined after death, but a man can be pronounced healthy up to a certain point, and so can a labour be pronounced normal up to a certain point. "This threat to supply the poor with midwifery practitioners only partly trained in midwifery and wholly untrained in medicine and surgery ....." There is no such threat. Our effort is to replace untrained midwives by trained midwives. Dr. Rentoul says that Dr. Matthews Duncan states that one woman in every fifteen died in her first confinement. Dr. Matthews Duncan never said anything of the kind. "The proposal to establish a partially trained class of midwifery practitioners for the poor only is a crime-producing proposal." There is no such proposal. The proposal is to replace untrained persons by trained persons. Dr. Rentoul asks if we are "therefore to hand over this branch of the practice of physic to persons whose poverty, if not their will, would press them to perform illegal operations?" We think that the better persons are trained and controlled the less likely they will be to do illegal things.

We observe other mis-statements, but we have mentioned enough. It should not, however, pass without notice that Dr. Rentoul holds the opinion that "the poorer classes can do without midwives," and that the public rates should pay for proper attention to parturient women, "that the fee should be uniform for all kinds of labour, and that such fee should be 40*s*." The midwife already exists in large numbers and cannot be suppressed by any words or schemes of Dr. Rentoul. The only practical question is, not how she shall be supplanted, but how she can be improved.

I am, Sirs, yours faithfully,

ROWLAND HUMPHREYS, L.R.C.P. LOND.,
Honorary Secretary Midwives Bill Committee.

12, Buckingham-street, Strand, W.C., Jan. 19th, 1897.

DR. R. R. RENTOUL'S ELECTION EXPENSES.

To the Editors of THE LANCET.

SIRS,—The result of the General Medical Council election must be gratifying to the supporters of Dr. Rentoul's policy. We, the undersigned, think this an opportune moment for bringing to the notice of these supporters the heavy expenditure in which it has involved Dr. Rentoul, the sum of £85 17*s*. 6*d*. having been spent by him in stamps, stationery, and travelling. We feel that practitioners upon whose behalf he has so faithfully striven should defray this out-of-pocket expenditure. Also, we would state that since 1890 Dr. Rentoul has spent £375 13*s*. 8*d*. in opposing the four Midwives Bills. Of this, £351 12*s*. 8½*d*. has at various times been refunded, thus leaving £24 0*s*. 11½*d*. still owing, exclusive of interest. Dr. Rentoul is, like most of ourselves, in general practice, and we feel it to be unfair to ask him to give not only his time and work (which have been and are invaluable to the cause) but also his money on our behalf. We, therefore, with confidence ask his supporters to subscribe to a fund for the repayment of this £109 18*s*. 5½*d*. By this means practitioners will show practical appreciation of good work done, and will pave the way for more. We would point out that this is not a question of a testimonial, although if the response were as hearty as it ought to be this might also be considered. It is firstly and chiefly a question of paying back money out of pocket, spent—and most cheerfully and usefully spent—in furthering our interests. At the same time we would add that no time should be lost in establishing a Guarantee Fund so as to be ready to fight the next Midwives Bill, and to help in drafting and securing the passing of a Bill for Increased Direct Representation upon the General Medical Council. For these purposes about £1500 will be required, and considering the handsome and prompt response of the profession in many cases—e.g., Dr. Cullingworth's expenses—no difficulty should be experienced in raising this money for such important objects. We have Dr. Rentoul's statement that he cannot advance any more money for these purposes, although he is both willing and ready to give both work and time.

Donations will be gladly received by Dr. A. Cox (Gateshead) and will with your permission be acknowledged in your columns.—We are, Sirs, yours truly,

"THE LATEST VIEWS ON PHTHISIS."

To the Editors of THE LANCET.

SIRS,—I have been very greatly interested in the letter of your correspondent at Rome on the above subject,[1] because in all the editions of my book I have mentioned facts tending to show that phthisis is quite as likely to prove a disease of nutrition as of infection, or a mixture of both; and, as will be seen in my third edition (p. 300), these facts have gained considerably in importance of late years. I should like also to direct the attention of your readers to the recent writings of Professor T. J. Mays of Philadelphia and his treatment of phthisis by excess of albuminous food and large and long-continued doses of strychnia.[2] I have recently had a case under my care which I showed at the Æsculapian Society treated by this method, in which the results appeared to be quite as good as those recorded in America, and greatly exceeded my previous expectations. I am well aware how dangerous it is in a disease like phthisis to build anything at all upon a few cases, and but for your correspondent's letter I should not have mentioned the matter just now. Still, I do think that the above facts are well worthy of the careful attention of those who, like the Milanese and some American pathologists, are prepared to look all round the bacillus.

I am, Sirs, yours faithfully,

Brook-street, W., Jan. 18th, 1897. ALEXANDER HAIG.

QUACKS AND UNCERTIFIED DEATHS.

To the Editors of THE LANCET.

SIRS,—The enclosed cutting from a weekly paper of some standing and with a large circulation in this county may be of interest to you as showing the publicity, and therefore encouragement, at times given by the press to the efforts of quack doctors to hoodwink the public.

In some districts in this county unqualified medical practice prevails extensively; in one urban district, for instance, of 18,000 population over 33 per cent. of the deaths during 1896 were uncertified, as the result of unqualified medical attendance; and the Durham county council, recognising the dangers of such practice and the fact that it interferes with the accuracy of the vital statistics and with the precautionary measures taken against the spread of infectious diseases, have, by representations to the Local Government Board, the Registrar-General, and the General Medical Council, been endeavouring to put a stop to such illegal practice. Such newspaper reports as the enclosed, however, are calculated to encourage unqualified practice and are in my opinion much to be regretted. The "Dr." Steele referred to in the cutting was a year or two ago successfully prosecuted and heavily fined for an offence against the 40th section of the Medical Act, 1858, his occupation to within eighteen months of the date of the prosecution having been that of a coalminer. Such punishment, however, instead of acting as a deterrent appears to have enlisted the sympathy for the offender of many persons in the district, with the result that not only has his practice not diminished, but he was very soon afterwards elected a member of the district council.

At their last meeting, I believe, the General Medical

Council decided to call the attention of the Registrar-General to the unsatisfactory practice adopted by some registrars of births and deaths of registering deaths uncertified as the result of unqualified medical practice without communicating with the coroner, and without doubt the holding of coroners' inquests with regard to all uncertified deaths is the most effective, if not the only practical, means of stamping out unqualified medical practice.

I am, Sirs, yours faithfully,

Durham, Jan. 19th, 1897. T. EUSTACE HILL.

*** Dr. Hill encloses a report from the *Durham County Advertiser* of a meeting at which "Mr. J. Tempest, M.D., L.L.D." (*sic*), of Accrington delivered an address on the "History of Medicine." The learned L.L.D. inveighed against the monopoly enjoyed by the medical profession in the treatment of suffering humanity, and against the action of a coroner in refusing to accept a death certificate from a person (not the "Dr." Steele above referred to) practising the "American Reform System of Medicine." The *Durham County Advertiser* must have been sadly in want of readable matter when it printed such mischievous nonsense.—ED. L.

"THE HALF-YEARLY MEETING OF THE FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND."

To the Editors of THE LANCET.

SIRS,—I have nothing more to say about Mr. Anderson, but as Mr. Rivington has referred to a portion of my speech which was not reported I may say that I pointed out that the same little clique which runs the Association of Fellows had also run Mr. Rivington for the General Medical Council, Mr. Anderson being one of the honorary secretaries of Mr. Rivington's committee. I denied then, as I do now, that Mr. Rivington's efforts on behalf of the Members had led *to the sacrifice of his collegiate interests* as put forth by his committee, and now that Mr. Rivington has supplied me with the date, 1886, I am able to prove it. In August, 1886, Mr. Rivington was a candidate for the post of Examiner, but was not elected because in the opinion of the Council there was a more eligible candidate. I find from your columns that Mr. Rivington took no part in the meeting of Fellows and Members in March, 1884, or November, 1885, and that at the meeting in November, 1886, he made his first speech on behalf of the Members. In a letter of the following week Mr. Rivington mentions that he wrote upon the subject in 1868, and later in his oration at the Hunterian Society and his Carmichael Essay, but I can assure him that none of these literary efforts in any way affected his non-election as an examiner. I am, Sirs, yours faithfully,

Cavendish-square, W., Jan. 18th, 1897. CHRISTOPHER HEATH.

PILOCARPINE IN ECLAMPSIA.

To the Editors of THE LANCET.

SIRS,—I regret that unexpected and unavoidable absence from the meeting of the Obstetrical Society of London on Wednesday, Jan. 6th, prevented my hearing the remarks of Dr. John Phillips and Dr. Herman on my notes of a case of eclampsia occurring at the fifth month, and in which the uterus was emptied. As these notes will be published in full I only take the opportunity of saying here that no one, after eighteen years of its employment, is better aware of the physiological effects of pilocarpine than myself or of the responsibility attaching to its use in certain cases. On the other hand, I desire emphatically to assert that in this particular instance it is my belief that it was the pilocarpine that ultimately saved the patient's life. It was injected but *once*, and in quantity only the tenth of a grain, and its use was followed after the immediate development of its physiological effects by rapid reduction of the high arterial tension, entire cessation of convulsions, which up to that moment had been of frequent recurrence, and the consequent return to consciousness of the patient. But it was not from the therapeutical aspect of the case that I was principally influenced in reporting it. There were several other points of considerable clinical interest—viz., retroversion of the uterus as a cause of the eclampsia, the retinal symptoms and appearances as indications of the approaching cerebral complications, the occurrence of glycosuria from the chloroform administered, and the rapid disappearance of the albuminuria which had been present in such quantity prior to the emptying of the uterus. The administration of such a remedy as pilocarpine must always depend on the circumstances of the individual case in which it is applied and the judgment of the practitioner who employs it. Nothing I said in my short paper could be construed into an advocacy of anything so rash as its routine employment in eclampsia.

I am, Sirs, yours faithfully,

H. MACNAUGHTON-JONES.

"A QUACK AND HIS VICTIM."

To the Editors of THE LANCET.

SIRS,—Will you allow me to state, in reference to your annotation on the prosecution of one George at Burnley for obtaining money by false pretences, that the Medical Defence Union initiated and paid the costs of the case? The result was most satisfactory, as the prisoner was sentenced to twelve months' imprisonment with hard labour.

I remain, Sirs, yours faithfully,

Jan. 19th, 1897. A. G. BATEMAN, M.B. Aberd., Gen. Sec.

HOSPITAL ABUSE.

(BY OUR SPECIAL COMMISSIONER.)

V.—MANCHESTER (*concluded*).[1]

Subscribing Patients.—The Competition of Charitable Provident Dispensaries.—The Lowering of the Standard of Work performed by Town Practitioners.

HAVING described at length what has been done to prevent abuse at the Royal Infirmary I must now consider briefly the position of some of the other large Manchester hospitals. There was, I found, a general consensus of opinion that little or no abuse existed at the Ancoats Hospital. The surrounding population is so extremely poor that one of the difficulties in treating the patients is their inability to obtain sufficient nutriment. For this reason those who could be treated as out-patients have sometimes to be sent to the Poor House Infirmary or taken as in-patients, so that they may receive sufficient food. One visiting physician attached to this hospital did, however, complain that general practitioners were apt to be very generous at other people's expense. If their paying patients were anxious for a second opinion they would give them a recommendation to a hospital, and thus secure for their patient this second opinion free of all cost.

A much better class of patients frequent the Hospital for Consumption and Diseases of the Throat. At this hospital the out-patients are called upon to contribute towards the expenses of the drugs. Most of the out-patients pay for their cod-liver oil and a few subscribe as much as 2*s.* 6*d.* a week for medicines. Some of these are certainly too well off to come to the hospital, but it is difficult to accuse a patient of abusing a charity when he pays half a crown a week. The acceptance of payments greatly complicates the situation, for it is then almost impossible to establish a wage limit or to know where to draw the line. This contribution for drugs is voluntary, but it is so considerable as to defray nearly the whole of the expenses. Thus in 1895 the expenditure for medicines and dispensary expenses is set down at £759 8*s.* 3*d.*, and the receipts of voluntary contributions from the out-patients amounted to £704 18*s.* 6*d.* These are remarkable figures, and whatever fault may be found with the principle involved it would be difficult to persuade the managers of the hospital to abandon a system which gives such advantageous practical

[1] The previous articles on this subject were published in THE LANCET on the following dates: (1) Sept. 26th, 1896, Plymouth and Devonport; (2) Oct. 10th, 1896, Exeter; (2 *continued*) Oct. 17th, 1896, Exeter; (3) Oct. 31st, 1896, St. Thomas's Hospital, London; (4) Nov. 14th, 1896, Liverpool; (4 *continued*) Nov. 21st, 1896, Liverpool; (4 *continued*) Dec. 12th, 1896, Liverpool; (5) Jan. 2nd, 1897, Manchester; and (5 *continued*) Jan. 9th, 1897, Manchester.

Hosted by Google

results. Also, the management naturally objects to the absolutely destitute. What is the use of medicine where there is not enough food? On the other hand, if the patient is not absolutely destitute, why should he not contribute, be it but a penny or two, towards the cost of his medicine? Abuses, however, naturally arise. Thus some patients who pay 2*s*. 6*d*. a week have no special illness. Their complaints are simple complaints. They do not stand in need of a second opinion or the constant advice of a consultant, and with the half-crown that they pay to the hospital they could obtain all that is necessary from an ordinary practitioner. By a more careful inquiry into the financial position of the patients this evil is being reduced; but it still exists. Thus while I was at the hospital a youth presented himself as an out-patient, and, in answer to questions, said he was not at work. On being further pressed he admitted that though he was not in regular employment he did work for his father, who was a joiner and builder. He estimated his father's income at thirty shillings a week which for a master builder was evidently below the mark. This case was referred to the secretary for inquiries. Another evil also results from the system of payment for medicines. An impression has gained ground that patients are not admitted who do not pay. This is very regrettable and quite against the object of the charity. The payments are only voluntary, and those who really cannot pay are welcome. They may even have cod-liver oil free of any charge. Nevertheless, on the day of my visit I found that only 7 per cent. of the out-patients had failed to contribute towards the cost of the medicines, and I was told that this was above the average.

Inquiries are made as to the financial condition of the patients who betray themselves by their language or dress. Yet if they make a fraudulent declaration as to their earnings, and this is discovered too late to prevent the admission of the patient, it is considered that there is no redress possible. Some applicants, however, at once declare they are able to pay, that they are under the treatment of a general practitioner, but want a second opinion. These patients are not accepted. They, however, sometimes further explain that though they can pay for their medicine and for the advice of a general practitioner they cannot pay a guinea for the advice of a consultant. In this case the visiting physician decides what should be done. If such applicants have an income of £3 or £4 a week the clerk, on his own responsibility, rejects them, or, to confirm this verdict, refers them to the secretary of the hospital. The number of applicants rejected is but small. It does not amount to one person per day, though there were 9373 new out-patients in 1894 and 8696 in 1895. Nor is there any attempt to enforce a distinct wage limit, for it is argued that some of the patients have not been working for some time because of their ill-health. For the in-patients of the hospital the inquiry is more strict, and as a consequence the subscriptions paid by the patients is much smaller. In 1895 there were 226 in-patients, showing a decrease on the two previous years. Their average stay in the hospital was sixty-three days. The cost amounted to an average of 15*s*. per week per patient and the average payments made by the in-patients amounted to 1*s*. 3*d*. per week. In 1894 this average was 1*s*. 1*d*. and in 1893 it was 1*s*. 6*d*.

One good point which I noted at this hospital, and, indeed, at most of the Manchester hospitals, is the dead set made against the system of recommendations. One of the consulting physicians related to me how, when he was at St. Thomas's Hospital, London, he had on one occasion to refuse two very urgent cases because some other and quite unimportant cases claimed admittance and had recommendations from a governor. According to the rule, he had no right to refuse the latter, and then there were no more beds available for the former and far more deserving cases. Recommendations are now almost done away with at the Manchester hospitals. The only argument in their favour is that some subscribers would be lost if they were deprived of this cheap form of patronage. But the loss thus occasioned would probably not be very great, and would be fully compensated by the reduction of prevalent abuses.

If the system of recommendations is thus disapproved and combated at the hospitals it is still in high favour with the provident dispensaries. For instance, at Hulme and Salford there are two charitable dispensaries to which employers and others subscribe and get recommendations in proportion to the amount of their subscription. Each recommendation entitles the bearer to three weeks' treatment. A large proportion of these recommendations are given by employers to their workpeople who could afford to pay. Also the public can go straight to the dispensaries, buy recommendations, and then fill up the ticket for themselves. The residential surgeon could certainly object to this; but in practice this is rarely done, especially if the surgeon intends ultimately to establish himself in the district. These dispensaries could not pay their way if they did not sell the recommendations and also sell drugs to the patients. It is a farce to call them charitable institutions when they are run on such a commercial basis. Nor is it surprising that the general practitioners should complain of the competition thus organised against them. As for these dispensaries making any serious inquiry concerning the financial means of their members all the general practitioners with whom I discussed the matter treated the suggestion with scorn. On their side, lay managers of dispensaries complain that medical men are not loyal to their profession or to the dispensaries. The medical men while in the service of a dispensary are interested in increasing the number of patients at their dispensary and are not over anxious to prevent abuses. Then, when the medical man has climbed up on the back of the dispensary and reached an independent position, he turns round and kicks the very institution where he himself created the abuses of which he now complains. As for sweating profits out of the medical profession, so far as the Manchester District Provident and Charity Organisation Society is concerned, the rule is that half the penny weekly subscription goes to the medical men and the whole of the 10*s*. midwifery fees. When all working expenses have been paid, two-thirds of the balance remaining in hand are given to the medical officers, and if there is any sweating it relates to the remaining third, which goes to constitute the reserve fund. Thus the lay managers of the dispensaries maintain that much of the abuse that exists is due to the indifference of the medical officers themselves, who have the power to reject patients. How far the control which the medical officers are said to be able to exercise is real I did not stop to inquire, as this is a question only indirectly connected with my present subject, and could be more appropriately discussed as part of the problem involved in the battle of the clubs. But it is quite certain that if the dispensary medical officers were very strict in rejecting patients who could afford to pay for private advice many disputes would arise between them and the lay members of the provident dispensaries. Such disputes have to be referred first to the board managing the local dispensary, and then can be brought before the Charity Organisation Society, which constitutes a sort of court of appeal. But as the latter is the parent of the former the question arises whether this is a truly impartial tribunal. In any case the complaints against the local provident dispensaries are, as I have already stated, numerous and bitter. They fail, we are told by the general practitioners, to act as a check upon the central hospitals. They do not divert the current of unsuitable cases from these hospitals; indeed, in some instances the belief is encouraged that the best means to gain admission to the hospital is to first join the provident dispensary. This accusation I found particularly applied to the Children's Hospital. Poor people were told to join the dispensary, and then they would get a recommendation from the dispensary to the hospital. Thus the dispensary receives the penny subscriptions from these poor people and the hospital does the work. How far this complaint is based on some isolated case or, on the contrary, arises from a more general and widespread abuse I am unable to say. All I now seek to bring forward is that these complaints, these accusations, have been made in my presence, with a view to my publishing the same. Whether or no these complaints are fully justified or somewhat exaggerated, they in any case serve to show the bitterness of feeling and the widespread discord and diversity of opinion between the medical men and the laymen who are concerned with the administration of medical charities.

In conversing with several general practitioners I noted a number of complaints which it seems to me deserve consideration. Thus one general practitioner insisted that many people now went to the hospital who a few years ago would have contrived to be attended at home. For instance, the general practitioner, often acting at the suggestion of his patient, called in a consulting surgeon, to whom the usual fee of two guineas was paid. Then the consulting surgeon was asked to exercise his influence at his hospital to obtain the admission of the patient, and thus the necessary operation was performed for nothing. But this comparatively

Hosted by Google

well-to-do patient occupied a bed which should be reserved for a much poorer class of people. Formerly, even very poor people, when some serious illness arose, were in the habit of gathering their friends together so as to raise a fund, and thus the operation or the expensive treatment was entrusted to a surgeon or physician, who received the usual fees. Now this rarely happened, for it was so much easier and, above all, so much cheaper to gain admission to a hospital. The money which in these cases used to go to the profession is now lost. Certainly some of the very ablest physicians and surgeons were on the staff of the hospitals, but how often was a patient obliged to content himself with the advice given by a student or by a nurse. Thus my informant had sent to the hospital one of his poor patients who was suffering from purulent ophthalmia. Yet though the patient had been there several times he had only seen the nurse. As for the abuse of hospitals one of my informant's patients had died in 1895 from pneumonia. During his last illness he had paid in medical fees the sum of £11. Then a consultant was sent for, to whom the two-guinea fee was given; but the patient recognised the consultant as the medical man who for several years had attended to him gratuitously at the hospital.

Why, I was asked, with some expressions of indignation, could not the medical profession be governed as well as that of the veterinary surgeons? The latter elected their own council and the council elected its own president. There was no confusing multitude of qualifications. The veterinary surgeons had but one diploma. Students in all parts of the country sit down to answer the same written question on the same day and at the same hour. A diploma wherever obtained was of equal value to all other diplomas and the profession was self-governed.

Several general practitioners expressed the opinion that the out-patients' department at the hospitals should be done away with altogether. If patients could wait for several hours in the out-patients' rooms they could not be very ill and, therefore, did not need the superior advice which, it is supposed, a poor man can only obtain at the hospital. Many patients, however, did not go to the hospital for advice; their object was to obtain medicine cheaply or gratuitously. This was unfair to the dispensing chemists. These tradesmen had also much to say against the hospitals. For instance, a person suffering from epilepsy will go to a hospital month after month simply to get his supply of medicine renewed, when it would cost him but little more to buy the same from a druggist.

The fact that the tendency to resort to the hospital is becoming more and more general not only reduces the income of the general practitioner, but it has a direct and disastrous effect in lowering his sense of dignity. The greater number of cases of infectious fever are now removed to the fever hospitals. If there is a fracture, or a special eye, ear, or throat case the patients all rush off to a hospital. Little of interest remains for the general practitioner. In large towns the old family medical man barely survives this competition. When a medical man goes to a family and remembers that he has brought into the world several of its members he feels that he is an old friend of the household. There is a link of affection and interest between him and his patients which converts his profession into a work of love and has an elevating, softening, and humanising effect. The medical man is proud of his calling and devotes his best abilities to his work. Nothing is so stimulating as the sense of respect which he inspires and the feeling of responsibility which weighs upon him. Nothing hurts a medical man more than to be treated as a tradesman. A poor patient who shows proper respect is preferable to the rich patient who thinks there is nothing else required from him but a good fee. It does not suffice to study financial conditions, a psychological analysis of the position of the general medical practitioner is also necessary. A brilliant house surgeon no sooner leaves his hospital to set up in general practice than he finds he has no longer any interesting cases—they all go to the hospital. A striking comparison might be established between the case-list of a town and a country practitioner. Formerly a town practitioner was considered to be the more skilful or the more experienced of the two. The tables have been entirely turned of late. For instance, I was told of a country practitioner who had in one week an amputation of the thigh, an operation for hernia, and a removal of the breast. In a town all these cases would have gone to the hospital. The general practitioner will cease to be a surgeon. In surgical cases he will at most be allowed to advise, to suggest, and to hold the sponge. This will tend to bring a totally different class of men into the profession. Commercial men will become general practitioners, for they will argue that they can earn a living without much trouble. They need not study, they will not assume any responsibility. they will win no glory, but they will not be troubled by any anxiety. They will not respect themselves and they will not be respected; but they may jog along easily, attending only to trivial, monotonous cases, and referring all other cases to the consultants or to the hospitals. The high medical education and training which medical men receive will be altogether useless. These men will have no difficult, responsible work to perform. There will be nothing ennobling about their profession. Yet it is to such a deplorable and degrading condition that the general practitioner is likely to be reduced by the competition of hospitals, specialists, and consultants. Such are some of the grievances of which the general practitioners complain; these grievances are felt very acutely and recently have found voice and expression in the agitation organised by the Manchester Medical Guild.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manchester Board of Guardians.

A PROJECT, which will, no doubt, soon be carried out by the Manchester board of guardians, illustrates not only the humane but the thoughtful and intelligent spirit in which they carry on their onerous work. The visiting committee of the Swinton Schools reported in favour of the erection of a cottage home in the school-grounds. Alderman M'Dougall, in moving the adoption of the proposal, said they knew the special attention that was bestowed on the training of girls who were going out to service, but it was felt that more was needed and that a cottage home would aid in securing more thorough domestic training. It is proposed to provide accommodation for ten girls in training for domestic service and for five infants between the ages of two and four, to be placed under the care of a foster-mother. It will, of course, be under the control of the master and matron. The presence of the infants will, it is thought, be useful in enabling the girls to become accustomed to washing and dressing and the general care of children. A small room is to be provided for each girl, so that she may look after it and acquire habits of tidiness. It is thought that it will be well ultimately to erect two homes. The proposal was seconded by a lady guardian, Mrs. Hyland, and adopted. This is a satisfactory move in the right direction. It was next proposed and seconded that the board's annual subscription to the Manchester Royal Infirmary should be renewed. One of the guardians, however, raised a curious objection. As a trustee of the infirmary "he was present at the recent meetings, at one of which Sir John Harwood stated that the infirmary board had a fund of £200,000, and that but for the possession of that money they would not have entered upon their re-building scheme. Under these circumstances the ratepayers had no right to contribute £74 a year." It was pointed out that every year hundreds of cases were sent to the Royal Infirmary that would otherwise have to be treated at the workhouse hospital. The motion was carried with two dissentients, who apparently ignored the fact, known to most Manchester people, that the question of the re-building and enlargement of the infirmary is an old one which has become more pressing year by year, and would not be less urgent if there were no money in hand wherewith to build. It was also resolved, subject to the approval of the Local Government Board, to give a subscription of £50, as last year, to the Manchester Jewish Board of Guardians, a voluntary association of Jewish gentlemen who do much to relieve their own necessitous poor and thereby relieve the city rates.

Opposition to the Manchester Sewage Scheme.

At the last meeting of the Mersey and Irwell Joint Committee Mr. T. W. Killick presented a report of the consulting sub-committee with reference to the Manchester Corporation Bill, 1897. One of the clauses of the Bill is to the effect that the corporation may discharge into the Mersey the effluent from the sewage works at Davyholme. This is

Hosted by Google

objected to on the ground that no provision is made that the effluent, either when turned into the effluent conduit at Davyhulme or when discharged into the Mersey at Thelwall, "shall be satisfactory, or such as the joint committee would allow." Mr. Killick moved that a petition should be presented against the Bill with the view of so amending Clause 25 as to provide specifically that the effluents whether at Davyhulme or at Thelwell, "shall be subject to the provisions of the Rivers Pollution Prevention Act, 1876, and the Mersey and Irwell Joint Committee Act, 1892." After a prolonged and somewhat acrimonious discussion and the rejection of an amendment, which was moved and seconded by the corporation members of the committee, by 12 to 3, the resolution was carried. At the same meeting "Sir Henry Roscoe was re-appointed chemical adviser to the joint committee for one year at a salary of £725, such sum to include travelling expenses." Some sympathy may be felt for the corporation members of the committee, and especially perhaps for Alderman Joseph Thompson, the vice-chairman, who was in the chair at this meeting, but did not vote. Punishing others for their misdeeds must give rise to emotions so very different from those produced when punishing themselves. Warrington seems also to be entering the lists against the Manchester Bill.

A Burial Scandal.

From some facts which transpired at the meeting of the Ashton-under-Lyne Town Council, on the 13th inst., it seems that some of the churchyards there are in a disgraceful and dangerous condition. The minutes of the Sanitary Committee contained a resolution to present copies of orders of the Privy Council regulating burials in Ashton to the rectors and the vicars of Christ Church and St. Peter's Church respectively. It appears that these orders have been ignored for years. A Mr. Pownall said that the orders were "irrational, impracticable, and impossible," and that "the rule that only one body should be buried in one grave was absolute nonsense." Mr. Kelsall spoke from a sanitary point of view and described burials when "from the awful stench the mourners had hurried away from the graves of their departed friends; he had seen foul gases oozing from the graveyard of Christ Church which reminded him of Dante's description of such exhalations being compared to the 'sighs of the damned.'" Allowing for this poetical imagary, it is clear that a bad state of things exists. He spoke of paupers being "buried in trenches, with a very little layer of earth between each, and how coffins had sunk in water and sawdust had been used to conceal the oozings of drainage into graves," which he said was the condition to-day. Cremation was suggested, but public feeling is scarcely ready for it to be made compulsory. The Town Clerk said that the Council was not responsible for the contravention of the orders of the Privy Council. But if the Corporation is the sanitary authority it is surely responsible for allowing this overcrowding of the graveyards to continue unchecked for years.

Manchester Medical Society.

At the annual meeting of the Manchester Medical Society, which was held at Owens College on Jan 13th, the following gentlemen were elected officers for the ensuing year:—President: Dr. Steell. Treasurer: Dr. Glascott. Secretary: Mr. W. Coates. Committee: Dr. Edge, Dr. Faulkner, Dr. T. A. Helme, Mr. H. Lund, Dr. Milligan, Dr. Railton, Dr. Reynolds, Dr. John Scott, Mr. W. P. Stocks, Dr. Torrop, Dr. Wild, and Mr. G. A. Wright. The society has at present 373 members and is in a prosperous condition; seven ordinary and three clinical meetings were held during the past year, with an average attendance of forty-four members. Whilst the phenomena of the Roentgen rays were as yet a scientific novelty the society gave a practical proof of its readiness to encourage research. After the delivery of an address by Professor Schuster in the chemical theatre at Owens College on the Medical and Surgical Aspects of Roentgen's Discovery,[1] the society established a guarantee fund for six months to provide for investigations to be undertaken in Professor Schuster's laboratory. At the end of the six months it was only found requisite to call in a fourth of the £200 which had been guaranteed, and it was not considered necessary to prolong the arrangement.

Jan. 19th.

[1] THE LANCET, March 28th, 1896, p. 892.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

A Conjoint Pathologist for Scottish Asylums.

AN important scheme is being matured in Scotland with a view to the appointment of a conjoint reserve pathologist for Scottish asylums. A meeting of a number of superintendents of asylums was held last month at which a committee was appointed to draw up a scheme; it consists of Dr. Clouston, Dr. Yellowlees, Dr. Urquhart, Dr. Carlyle, Dr. Johnstone, Dr. Macpherson, and Dr. G. M. Robertson. It is proposed that the various asylums should contribute a sum of £500, of which £400 should be paid to the pathologist appointed. It is hoped that accommodation may be obtained in the new buildings occupied by the Royal College of Physicians' Laboratory in Edinburgh. The pathologist's duties are set forth as follows:—1. To examine material sent from the asylums and to furnish reports. 2. To carry on original researches upon the pathology of insanity. 3. To give instruction to members of the medical staff of associated asylums, free of charge, in the pathology of mental diseases and in laboratory methods. 4. To assist, if required, the medical staff of associated asylums in pathological researches. 5. He shall devote his whole time to the duties of his office.

University of St. Andrews.

At a meeting of the University Court, on the 13th inst., plans of a proposed building for the accommodation of the medical classes were submitted. The site selected is within St. Mary's College gardens. It was decided to proceed with the buildings as soon as the necessary funds could be procured. This essential condition, however, was promptly realised, for immediately after the decision was taken the Lord Rector, the Marquis of Bute, announced that, provided a proper guarantee were provided securing the building for the purpose for which it is to be erected he himself would be at the expense of erecting it. This was agreed to and a vote of thanks passed to his Lordship. The Marquis of Bute also intimated his willingness to provide salaries for the lecturers on physiology and modern Greek during the next two years. Miss Umpherston, L.R.C.P. Edin., was appointed to be lecturer on physiology. It was agreed to raise the salary of the Chandos chair of Medicine and Anatomy to £500, exclusive of fees, by addition from the Berry bequest fund.

Maternity Hospital for Dundee.

The sum of £5000 having been devoted to this purpose in the Cobb bequest, the directors of the Dundee Infirmary were approached on the matter and undertook to found and maintain a maternity hospital provided the sum of £10,000 were placed in their hands. The additional £5000 has now been raised by subscription and the entire sum handed over to the infirmary directors.

Presentations to Medical Men.

Mr. H. E. Jones, M.B. Glasg., of Glasgow has been presented with a barometer by the members of the ambulance class he has recently conducted on behalf of the Scottish Girls' Friendly Society.—Dr. Duncan Macartney has also received a presentation from the members of his ambulance class.—At a recent meeting of the members of the Grove-street Institute, Glasgow, an address embodying a vote of thanks was presented to Mr David Dinwoodie, M.B., in acknowledgment of a course of lectures he has recently delivered in the institute.

New Fever Hospital for Dumbarton.

The local authorities of the burgh of Dumbarton and the western district committee of the county council have agreed to the erection of a joint hospital for the reception of cases of infectious disease.

Glasgow University.

The following awards of bursaries and prizes in the faculty of medicine have been intimated: Brisbane bursary of £42 for four years—C. C. Cuthbert, M.A.; Highland Societies Bursaries, £25 each for four years—A. Maclean and J. Stewart, M.A.; Lorimer Bursaries, each £20 for three years—J. D. Lickley and Allen Martin, M.A.; Merchants' House Bursary, £25 for four years—F. J. Henry; Mackintosh Bursary, £30 for one year—T. Hunter, M.A., B.Sc.; Senior Arnott Prize (25) for an examination in physiological physics—A. L. Watson, M.A.; Junior Arnott Prize (£15)—R. M. Clark. At the January meeting of the Queen

Hosted by Google

Margaret College Medical Club an address was delivered by Dr. C. O. Hawthorne on "Some of the Aspects of the Mental Discipline associated with the Study of Medicine."

The Scottish Poor-law Medical Officers' Association.

The Scottish Poor-law Medical Officers' Association, which was formed towards the close of 1895, has been several times mentioned in the columns of THE LANCET. Its objects are to raise the status of poor-law medical officers and to provide a channel through which all defects in the poor-law medical service may be brought to light and discussed, with a view to their removal. All past and present poor-law medical officers residing in Scotland are eligible for membership, and all persons interested in poor-law medical reform are eligible for election as honorary members at any general meeting. The first meeting took place on Dec. 9th, 1895, and the council will submit their report on the first year's working at the annual meeting to be held in the North British Station Hotel, George-square, Glasgow, on Jan. 27th. The council made every endeavour to have Scotland included in the scope of the Poor-law Officers' Superannuation Bill, which passed into law last session, but it was found that there were insuperable obstacles of a technical nature. In pursuance of this object deputations to the Local Government Board and to the Secretary for Scotland proceeded to Edinburgh; a deputation also visited London for the purpose of interviewing members of Parliament, and a numerously signed petition was presented to Parliament by Mr. Alexander Cross, M.P. for Camlachie (Glasgow). Much attention has also been given to the subject of tenure of office. Poor-law medical officers in England can only be removed from their appointments with the consent of the Local Government Board, but parish councils in Scotland claim that they can appoint and dismiss medical officers at pleasure without any control on the part of the Local Government Board. This matter was discussed at the British Medical Association meeting in Carlisle, and has been brought before the Local Government Board with a view to a decision being arrived at. Dr. William Bruce (Dingwall), Direct Representative for Scotland in the General Medical Council, is the honorary president of the association, and the secretary is Dr. Alexander M. Murdoch, 17, Broad-street, Mile-end, Glasgow.

Sanitary Work in Aberdeen.

During 1896 the sanitary staff of the city paid 17.890 visits in regard to infectious diseases and disinfected 4314 houses where cases occurred. 1558 patients were removed to hospitals and 4430 patients supervised at their homes. There were 4848 inspections in the unwholesome food branch, and 64¼ tons of meat, &c. (including 88,186 lb. of fish and 45,022½ lb. of beef), were seized and destroyed, or sold for manure, chiefly with the consent of the owners. Of 205 seizures only 6 had to be dealt with by magistrates; legal proceedings were instituted in 5 cases, and the fines imposed amounted to £28. Considering the magnitude of the fishing industry and of the provision trade in Aberdeen there was thus little attempt to dispose of objectionable articles for human food.

University of Aberdeen.

The "squatters" who took possession of the old premises in Longacre and lived there without paying any rent have now all been ejected so as to allow the building of the new south wing at Marischal College to be proceeded with. These poor people are being temporarily housed in the premises which will shortly have to be demolished to permit of the erection of the corporation model lodging-house. The University Court has declined to commit itself at this stage as to the most appropriate mode of celebrating locally the Queen's "diamond jubilee." This attitude is held to mean that a movement to improve the University buildings extension fund will be made. A scheme for erecting, at a cost of £3000, a marine laboratory and aquarium, the scientific work in which would be undertaken by the University, also finds favour.

Jan. 19th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Royal College of Surgeons in Ireland.

MR. ROBERT LAFAYETTE SWAN has just been elected Vice-President of the Royal College of Surgeons in succession to Mr. Kendal Franks, who, it will be remembered, resigned that office before leaving Dublin for South Africa. The place on the College council rendered vacant by the election of Mr. Swan was conferred on Dr. Lambert Ormsby. On Saturday evening Mr. William Thomson entertained at dinner his Excellency the Lord-Lieutenant and a numerous company.

Sending Patients to Unqualified Practitioners.

It would seem that at last the objectionable practice which prevails on the part of boards of Poor-law guardians in some parts of Ireland of sending patients threatened with hydrophobia to be treated by unqualified practitioners is about to be stopped. According to the *Newry Telegraph* the Local Government Board have decided that the sending of patients suffering from hydrophobia to McGovern of Cavan for treatment is illegal, and proceedings are about to be instituted in a test case against certain Poor-law guardians of the Newry Union for sending patients of this class to McGovern.

Dublin Hospital Fêtes.

A number of entertainments have recently been given here in support of the smaller city hospitals. On Saturday a performance in aid of the Children's Hospital, Temple-street, was given at the Star Theatre of Varieties under the special patronage of his Excellency the Lord-Lieutenant and the Countess Cadogan, while on Monday evening there was a most successful amateur representation of Mr. Sydney Grundy's comedy, "A Pair of Spectacles," at the Ancient Concert Rooms, the proceeds of which are to be given to the National Lying-in Hospital, Hollis-street.

The Beri-beri Epidemic.

At the last meeting of the board of governors of the Richmond Asylum Mr. Donelan, the acting medical superintendent, reported that the epidemic of beri-beri was distinctly on the decrease, only 1 case having been admitted to hospital since the previous board meeting. The numbers still under treatment are 26 men and 36 women, the total number treated from the commencement of the outbreak to the present time being 115, including 7 nurses. The board authorised the employment of a special nurse trained in the art of massage for the benefit of some of the patients of a paralytic and chronic type, and a skilled "masseuse" has accordingly been obtained from the Mater Misericordiæ Hospital.

The Admission of Cases of Delirium Tremens into Workhouses.

At a meeting of the Belfast board of guardians, held on Jan. 12th, it was decided that persons suffering from the effects of delirium tremens should be admitted to the workhouse and charged the full cost of their maintenance. As an indication of the extraordinarily defective working of the Irish Poor-law system, a guardian stated that a few weeks before a man had died in the Belfast Workhouse, leaving a legacy of £200 to an orphan society and having £4000 in the bank.

Coleraine Cottage Hospital.

At the annual meeting, held on Jan. 12th, the necessity of increasing the accommodation at this hospital was considered, and the committee were empowered to undertake this extension. A plan has been prepared by which two more wards or rooms can be provided for an increase in the rent of £10 yearly.

Curious Charms for Whooping-cough.

Considerable astonishment and amusement has been caused in Belfast by a case investigated at the coroner's court in which the treatment of whooping-cough by the passing of the child affected three times under a donkey was referred to. In his most amusing book, "Seventy Years of Irish Life," W. R. Le Fanu tells of two modes of dealing with the whooping-cough or "chin cough," as it is so generally called by the country people. One is this. If anyone should be seen riding on a piebald horse the father or mother of the person affected runs after him crying: "You that rides the piebald horse, what's good for the chin-cough?" Whatever the rider suggests is procured and given to the sufferer. This remedy is considered a very sure one by the peasantry, but is difficult to procure, as a man riding a piebald horse is not met with every day. The other mode of curing the disease is not considered so certain, but can more easily be procured, that is, passing the child three times over and under a donkey. Some donkeys are better than others. I remember a famous one in the southern part of county Down in which the rustics had great faith, and Le Fanu tells of one in county Cork so famous for curative powers that the owner, Ned Sullivan, supported himself and a large

Hosted by Google

family on what this remarkable donkey earned for him. This man used to perambulate the city of Cork and the surrounding neighbourhood with his ass, crying out: "Will anyone come under my ass for the chin-cough?" Two other charms which I have known to be used in county Down for this disease—and it is curious that whooping-cough and erysipelas (the rose, as the Irish peasants often call it) are the affections most treated by charms—are the administration to the patient of two kinds of foods (solid and liquid) obtained from two first cousins who are married, and soup made from the tails of mice. Staying several years ago with an uncle and aunt who were full cousins I was amused at the parents of children with whooping-cough coming to them for two different articles of food for their sick children.

The Forster Green Hospital for Phthisis.

The first annual meeting of the Forster Green Hospital for Consumption and Chest Diseases was held in Belfast on Jan. 15th. On Nov. 2nd, 1896, the Master of the Rolls sanctioned the amalgamation of the Belfast Hospital for Consumption with the Forster Green Hospital. The receipts for current expenses from all sources amounted to £1065 4*s.* 9*d.*, while the expenditure was £1035 8*s.* 9*d.*, leaving a balance of £29 16*s.* in the hands of the treasurer. The endowment fund has been increased by donations amounting to £140. Rapid progress has been made with the alterations and additions at Fortbreda House, the place presented by Mr. Forster Green, for the new hospital. During the year there were 796 new extern and 97 new intern patients. The Marquis of Dufferin and Ava was present at the meeting and made one of his most admirable speeches and stated that in view of the fact that phthisis had been a special scourge and curse to the city of Belfast and the north of Ireland generally he thought he might fairly plead that that hospital for the reception of phthisical patients was at all events as worthy of their support and contributions as, if not more worthy than, almost any other which could be mentioned in the neighbourhood.

The late Mr. James McKee, M.R.C.S. Eng., L.R.C.P. Irel.

I regret to report the death of Mr. McKee of Randalstown, county Antrim, one of the oldest medical practitioners in the north of Ireland, which took place on Jan. 16th.

Jan. 19th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

"The Accursed Knife."

THE phrase is Antonio Gallenga's, who loved his compatriots too well to spare the correcting rod. Cutting and wounding is the most frequent and also the most fatal of Italian crimes, causing, as the eminent criminal statistician, Baron Garofalo, demonstrated, "a homicide every two hours." It would be a curious and instructive inquiry, that of ascertaining how far offences are aggravated by the medium through which they take effect—drunkenness, for example, being a more brutal phenomenon when the drinker incurs it with ardent spirits and not with wine or beer. Similarly, personal violence is one thing when it takes the form of fisticuffs and quite another when it is inflicted with the knife. A people, not necessarily more depraved, may appear technically more "criminal" by giving vent to its passions or propensities, not in themselves worse, through agencies of deadlier power. Italy possesses an unhappy priority in lethal offences, and Northern exceeds Southern Europe in drunkenness, just because in the one case the knife is used instead of "nature's weapons" and in the other because raw whisky is the available beverage and not the juice of the grape. The Italian Senate last week, on the initiative of the Marchese Vitelleschi, had a full-dress debate on the prevalence, nay, the increase, of "reati di sangue" (crimes of blood) during the last decennium, and many were the causes, primary and secondary, adduced in explanation of the fact. The Marchese Vitelleschi saw much that was answerable for these crimes in the lack of sound education, even where it is given at all, deploring, for example, the total suppression of religious instruction in schools. Again, he thought the abolition of capital punishment directly favourable to homicide. To some of his arguments the Minister of Grace and Justice (Costa) replied, not ineffectively. Admitting the prevalence of lethal crime, his Excellency showed that it was not universally diffused throughout the kingdom—that (as, indeed, THE LANCET put *en évidence* some weeks ago) the Southern provinces contribute to these crimes out of all proportion to their population. This would confirm the Marchese Vitelleschi in his impeachment of defective schooling as a cause, these provinces being far ahead of the north in the number of *analfabeti* (unlettered). On the other hand, his Excellency distinctly "scored" when he drew attention to the striking fact that in Italy alcoholic excess is not attended with increase of violence. The provinces of Italy where homicides are most frequent are, he proved, precisely those where the lower orders are exemplary for their sobriety and abstemiousness. His Excellency was less fortunate in rebutting a charge as to the apathy of the public in presence of such "reati di sangue." Indeed, the supineness of Italians—the absence of all "sense of citizenship"—runs through their whole attitude towards every detail of national life, from representative government downwards. But, again, his Excellency redressed the balance in his favour when he proved that the suppression of religious (as distinct from secular) education in schools had nothing to do with the increase of lethal crime. "Nel 1870," he said, "nel Lazio, ove pure vi era istruzione religiosa più che obbligatoria, vi erano molti più omicidi" (In 1870, in Latium, where there was also religious instruction more than compulsory, there were also many more homicides). But the abolition of capital punishments he did not at all succeed in justifying. Thirty years ago in the House of Commons the whole subject was threshed out thoroughly, one of the most powerful speeches in favour of such punishments being John Stuart Mill's, who, on the ground of humanity, advocated execution as preferable to the slow torture of lifelong imprisonment with, or still more without, hard labour. But the speech of the occasion was Sir George Bowyer's, who, in answer to the plea that capital punishment was not a deterrent, adduced the following fact. A Neapolitan wanted to kill his wife. The guillotine was still the penalty for murder in the kingdom of the Two Sicilies, so he took her to Tuscany, where that penalty had been abolished, and put her to death there. Yet, in spite of that historical debate on the subject—in spite of the fact that Switzerland, having abolished capital punishments, was compelled by sad experience to legalise them once more, the Italian Government (though not without numerous and authoritative dissentients) made the abolition of these punishments the law of the land; and we now find the Minister of Grace and Justice defending that "reform" in presence of "a homicide every two hours"! The truth is that Italy, in many aspects of her life, has not emerged from the Middle Ages; that hardness of living at once inspires crime and robs detention in prison of its terrors; that the administration of justice is so perfunctory that the people, knife in hand, settle their differences among themselves; that, in fact, D'Azeglio's watchword thirty-five years ago—"Now we have to make Italians—" has lost none of its significance; and that Italy's most dutiful sons are those who, like the mass of her medical men, act strenuously in the spirit of that watchword, beginning with the rising generation and so guiding its growth as to exclude the vicious, and give the healthy subjects such advantages of training and environment as can alone form the ground-work of a civilised and progressive State.

Jan. 16th.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Syphilitic Sero-fibrinous Pericarditis.

SYPHILITIC changes in the muscle of the heart are not very uncommon, but cases of pericarditis from syphilis are of such rarity that Mracek, who had thoroughly investigated the literature of this question, could state: "Syphilis has hardly ever caused an exudative sero-fibrinous pericarditis." A communication of Professor A. Genersich in the columns of the *Orvosi Hetilap* describing a case of this kind is therefore of great interest. Professor Genersich, on examining the body of a man, aged thirty-two years, who had died from pericarditis, found various syphilitic lesions in different parts of the body, especially in the lung, the spleen, the liver, and the bones. The

Hosted by Google

pleura and the heart also exhibited gummatous growths of various sizes. The pericardium was found to be inflamed, its connective tissue being thickened, infiltrated, and full of round and fibroblast cells. The superficial layers of the pericardium showed a fibrinoid structure containing sparse endothelial cells and red blood corpuscles. The diagnosis of syphilis being established beyond doubt by the changes found post mortem in the various organs, Professor Genersich had no hesitation in attributing the signs of chronic inflammation found in the pericardium to the same disease.

Prolonged Anuria.

A highly interesting case was narrated by Professor J. Réczey at a recent meeting of the Budapest Hospital Association. A man, aged forty-five years, who had suffered from renal calculi for ten years, came to Professor Réczey's clinic with the statement that he had not passed urine during the last four days. On introducing a catheter the bladder was found to be empty. On percussion the area of the renal dulness was not found enlarged on either side. The patient being very stout palpation gave no satisfactory result. No operative interference was decided upon, the man feeling no discomfort whatever. Diuretics, such as Salvator water and dilute nitric acid, were freely administered and daily hot baths and injections of pilocarpine given with a view of preventing uræmia. The patient continued under observation at the clinic for ten days without any change taking place, but on the evening of the eleventh day he was suddenly seized with a violent desire to micturate, and four calculi, one of the size of a bean and three of the size of hemp seeds, came away without marked difficulty. During the following night he passed seven litres (= twelve pints) of urine. Professor Réczey pointed out that this case proved that obstruction of the ureter does not necessarily cause renal colic, and that obstruction even of both ureters may continue for some time without giving rise to urgent symptoms.

A Case of Tetanus treated with Antitoxin.

A student of the Budapest Veterinary College who had been bitten by an ape on the palm of his left hand was imprudent enough to dissect on the same day a horse which had died from tetanus, and on the following night was seized with pains in his left hand, but waited till next morning, when he went to Professor Réczey's clinic. The wound of the hand was at once enlarged, thoroughly cleansed with a solution of perchloride of mercury, and subsequently cauterised with caustic potash. He was then sent home, and although advised to present himself at the clinic next day did not do so, but stayed at home, where he was seized on the following night (Nov. 12th) with tetanic convulsions. A neighbouring practitioner who was called in ordered large doses of chloral-hydrate to be taken every two hours. On Nov. 13th the convulsions increased in frequency and intensity. The patient was conscious, his secretions and excretions were normal, he perspired freely, and his temperature was 42° C. (= 107·3° F.). He was now given a subcutaneous injection of pilocarpine, which arrested the convulsions for a few hours, but in the evening he was seized again every thirty minutes with convulsions lasting from a minute to a minute and a half. On Nov. 14th pilocarpine was again administered, giving relief for several hours. On Nov. 15th the pilocarpine ceased to be effective, the convulsion came on again twice every hour, and sometimes respiration stopped owing to the spasm of the respiratory muscles, so that artificial respiration had to be resorted to. It was consequently resolved to give the tetanus antitoxin a trial. The antitoxin was given in doses of 3 c.c. thrice daily on Nov. 15th, 16th, and 17th, and once on Nov. 18th. The patient's nights were quieter from the beginning of this treatment, and the last of the fits occurred during the night between Nov. 17th and 18th. He has been free from convulsions ever since and may be safely considered as recovered. His highest temperature was 43·2° C. (= 109·7° F.) on Nov. 17th, and the lowest was 35·2° C. (= 95·3° F.) on Nov. 20th. The special features of this case were: (1) The early development of the tetanus, the period of incubation lasting generally from eight to fourteen days; this rapid onset may be attributed to the obvious fact that the disease was in this case not due to bacillary infection, but rather to the absorption of toxins; (2) the absence of trismus and the absence of troubles connected with the secretory and excretory functions; and (3) the marked predominance of very violent clonic convulsions, the characteristic tonic contractions being but little marked.

Jan. 15th.

Obituary.

FREDERIC JOHN MOUAT, M.D., LL.D. EDIN., F.R.C.S. ENG.

BY the death of Dr. F. J. Mouat, which occurred at Durham-villas, Kensington, on Jan. 12th, the Indian Medical Service has lost one of the ablest and most distinguished of its older members. Anglo-Indian medical officers have made reputations for themselves in various lines of useful work. Dr. Mouat's principal claims to remembrance will probably be his zeal and success as an educational reformer and the improvements which he was the means of introducing into the prison system in India. Many of his personal characteristics specially qualified him for undertaking such arduous and responsible labours. His mental alertness and versatility, his talents for organisation, his power of making friends, and his knowledge of character all aided him in accomplishing an amount of work in various departments which will give him a permanent place in history among the administrative benefactors of our Indian possessions.

Dr. Mouat was born at Maidstone in 1816, studied medicine in London, Edinburgh, and Paris, and became a Member of the Royal College of Surgeons of England in 1838. In 1839 he graduated as M.D. at Edinburgh University and was appointed assistant surgeon to the Bengal Establishment in January, 1840. He arrived at Calcutta in June, 1840, and was shortly afterwards attached successively to the 21st Fusiliers (then at Fort William), to the 47th Bengal Native Infantry, and to the 1st Battalion of Artillery at Dum-Dum. Towards the end of 1840 he received the appointments of deputy apothecary and assistant opium examiner to the Government, appointments which afforded valuable opportunities to a young man having a taste for practical chemistry. During the year that he continued at this work he made investigations for the Liverpool Chamber of Commerce regarding some lichens which yield dye-stuffs and drew up a memorandum on Indian industrial products. The business capacity and technical knowledge which he then displayed induced Lord Auckland—at that time Governor-General—to appoint Dr. Mouat Professor of Chemistry and Materia Medica in the Bengal Medical College in 1841. With the duties of this chair he combined those of secretary, treasurer, and resident officer, having, in fact, general charge of the institution. Between 1841 and 1853 Dr. Mouat effected important reforms in the Medical College, especially in the introduction of an improved system of clinical instruction. He also obtained its recognition by the Royal College of Surgeons of England and the University of London, improved the finances of the hospital in connexion with it, formed a Bengali class, wrote an Atlas of Anatomy with descriptive letterpress in English and Hindustani, and translated the London Pharmacopœia into Hindustani for the use of the military class. He was also for two years chemical examiner to the Government. Dr. Mouat's chemical knowledge found an important practical application in connexion with the manufacture of percussion caps, field rockets, and other military explosives. While making these experiments he was attached to the Select Committee on Artillery at Dum-Dum, where, in conjunction with Colonel Edward Ludlow, he invented a waterproof varnish for protecting the detonating composition against atmospheric influences. The percussion caps invented by Dr. Mouat were the first that were made in India and were used in the China Expedition under Sir Hugh Gough. Dr. Mouat was also the first investigator of the chemical properties of gutta percha; before this substance was known in Europe he had published an account of it in the Journal of the Agricultural Society of Bengal. In April, 1843, Dr. Mouat was appointed secretary to the Council of Education of Bengal, a position which gave him the control of education in the Lower Provinces, and which he held for ten years, simultaneously with his work at the Medical College. In 1846 he brought forward a scheme for the establishment of universities in India. His proposals were adopted by the Council of Education and were approved by the Government of India, but were not sanctioned by the Honourable Court of Directors till 1854. Dr. Mouat was, therefore, the originator of universities in India, no one before him having succeeded in directing attention to the advantages which would result from such an enlargement

Hosted by Google

of the educational facilities of the country. In 1844 he was admitted to the Fellowship of the Royal College of Surgeons of England. In 1845 Dr. Mouat accepted the Professorship of Medical Jurisprudence in exchange for that of Chemistry; in 1849 he became Professor of Medicine and Clinical Medicine, with charge of the medical wards of the hospital, and in 1853 on the opening of the new hospital the designation of this last appointment was altered to that of Professor of Medicine and First Physician to the Medical College Hospital. In 1855 he acted as Presidency Surgeon for some months. In December, 1855, he was gazetted Inspector-General of Gaols in Bengal, and soon introduced remunerative forms of labour into the establishments under his control with such good effect that four of these prisons repaid the whole of their cost, and up to March, 1867, the prison manufactures yielded a net profit of Rs. 31,96,049, after payment of the whole cost of production. Another important feature in his scheme of prison reform was the employment of prisoners to some extent in the maintenance of order and discipline, such employment having a most salutary effect in encouraging the better nature of those who had not degenerated into habitual offenders. In November, 1857, during the Sepoy Mutiny, Dr. Mouat was sent to the Andaman Islands as president of a committee charged with the selection of a site for a convict settlement. The party had to encounter much hostility from the aborigines, and several of them were injured. Dr. Mouat was wounded in the mouth and had two ribs broken, but nevertheless continued his responsible duties as leader of the expedition, which succeeded in its objects and returned to Calcutta without loss. Both Lord Canning and the Home Government expressed much satisfaction with the manner in which the work of the expedition under Dr. Mouat was accomplished. A harbour discovered by the party on the West Coast of the Great Andamans, opposite to Port Blair, was named Port Mouat. Dr. Mouat was twice appointed to conduct inquiries into the subject of coolie emigration and on both occasions he received the thanks of the Government. In 1851 he founded the Bethune Society in Calcutta to promote a more intimate union between educated natives and Europeans. In 1854, when he was about to proceed to England on a year's furlough, he was presented by the graduates of the Calcutta Medical College with an address and a silver vase, and by the members of the Bethune Society with an address and a silver inkstand. In 1870, when he finally retired from the Indian service, he was presented by both the Hindoo and Mohammedan communities of Calcutta with addresses expressing their grateful appreciation of the benefits which he had been the means of conferring on them. On his return to England he was appointed one of the medical inspectors of the Local Government Board and discharged his duties in this new capacity with exemplary thoroughness until in 1887 failing health rendered it necessary for him to seek repose. Even then, however, his activity continued. His address as President of the Royal Statistical Society appeared in THE LANCET in November, 1890, and during the ensuing three years our columns contained long and important contributions from his pen on such varied subjects as the ethics of opium and alcohol and the organisation of medical relief in the metropolis. Dr. Mouat's contributions to the literature of medicine, philanthropy, and social progress include, in addition to the treatises already mentioned, "Prison Discipline and Statistics" (three papers), Journal of the Statistical Society of London; "Prison System of India," Transactions of the International Peniten. Congress; "Prison Labour," Journal of the Society of Arts; "Medical Statistics of Cholera and Syphilis" and "Notes on Medical Statistics" (Public Health Section of the Ninth International Statistical Congress), Transactions of the Epidemiological Society; "Statistics of Childbirth and Deaths therefrom in Workhouse Infirmaries from 1871-80," International Medical Congress; "History of the Statistical Society of London," 1885; "Origin and Progress of Universities in India," 1888; "Boarding-out of Orphans in England" and "International Prison Statistics," International Prisons Congress, 1890; and "Prison Ethics and Prison Labour," 1891. Dr. Mouat was also joint author with Sir Douglas Galton of "Hospital Construction and Management," 1883.

DONALD ALEXANDER FRASER, M.D. BRUX., M.R.C.S. ENG., L.S.A.

DR. D. A. FRASER died at his residence, Pomeroy House, Bridgetown, Totnes, on Jan. 11th, after a short illness. The deceased was the eldest son of Mr. P. Gordon Fraser, late colonial secretary for Tasmania. He was educated at King's School, Bruton, and received his medical education at St. Mary's Hospital, London, obtaining the M.R.C.S. Eng. and L.S.A. in 1880 and the M.D. of Brussels in 1886. Dr. Fraser went to Totnes ten years ago, being taken into partnership by Mr. J. C. Hains, J.P. The deceased was deputy coroner for the southern division of Devonshire and medical officer of health for the borough of Totnes. He also held the appointment of medical officer and public vaccinator for the No. 4 district of the Totnes Union. Dr. Fraser was extremely popular and held in the highest esteem both by the local members of the profession and by his fellow townsmen. He was forty-five years of age at the time of his death and leaves a widow and two young children, for whom much sympathy is felt.

JOHN WILFORD MARSH, M.R.C.S. ENG., L.S.A.

JOHN WILFORD MARSH, for many years connected with the Lincoln County Asylum, died on Jan. 14th, aged fifty-four years, at Bognor, Sussex. Since 1883 he had held the position of medical superintendent of Bracebridge Asylum, but about a year ago his health broke down and he retired to Bognor. The deceased gentleman was an old pupil of the London Hospital Medical School, where at one time he was house surgeon and clinical medical assistant. He was a member of the Medico-Psychological Association.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. T. Plücker, Professor of Special Surgery and Dermatology in Liége. For several months past, it seems, he was aware that he was the subject of a necessarily fatal disease and made various preparations for his death without making his family anxious or betraying his own cognisance of his state. Thus he told his students he should expedite his course of lectures, but that he should not probably be present at the examinations, and he declined various posts offered to him. In his will he particularly requested that those attending his funeral should keep their heads covered, knowing that the weather would probably be cold. He is much regretted by the local profession.—Dr. Thiry, formerly Professor of Surgical Pathology and Rector of the University of Brussels, at the age of eighty.—Dr. Wilhelm Theodor von Renz, Bath Physician at Wildbad. He had written a good deal on the history and therapeutics of the Wildbad springs, and had published a work on Trichinosis.—Dr. Michael of Hamburg, a well-known laryngologist.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the Second Examination of the Board in the subjects indicated at a meeting of the Board of Examiners on Monday, Jan. 11th, 1897:—

Anatomy and Physiology.—Arthur Greene Brinton, Charles York Flewitt, James Christopher Oates, Oswald Erasmus Ward, and Edwin Edgar Montague Price of Mason College, Birmingham; David Morgan Davies and George Herbert Simpson of St. Mungo's College, Glasgow; Robert James Fyffe of Firth College, Sheffield; William Nichols Blatchford of University College, Bristol; Robert Walker of St. Bartholomew's Hospital; John Samuel Cousins of Guy's Hospital and Mr. Cooke's School of Anatomy and Physiology; Joseph Bernard Thompson of University College, London; Edmund Hudson of Owens College, Manchester, and St. Thomas's Hospital; and William Stuart Low of Royal College of Surgeons and the University, Edinburgh, and St. Thomas's Hospital.

Anatomy only.—Alexander Septimus Arkle, Cambridge University, St. Thomas's Hospital, and University College, Liverpool; Hilt Mussenden Leathes, Cambridge University and St. Thomas's Hospital; Louis Charles Martin, Guy's Hospital and Mr. Cooke's School of Anatomy and Physiology; Emilio Frederico Crabtree, St. Bartholomew's Hospital; and Rustom Pestonjee, Ceylon Medical College and Mr. Cooke's School of Anatomy and Physiology.

Physiology only.—William Beck, Aberdeen and Edinburgh Universities, and John Alfred Mellish, St. George's Hospital.

Eighteen gentlemen were referred in both subjects, one in Anatomy only, and one in Physiology only.

Tuesday, Jan. 12th:

Anatomy and Physiology.—Percival Thomas Nicholls, Middlesex Hospital; Harry Norman Rex Child, Otago University, Dunedin, and Middlesex Hospital; Harold Burrows, Henry Warwick Illius-

Hosted by Google

John Warwick Illius, Walter Percy Dyer, and Thomas Warren Brown, St. Bartholomew's Hospital; Archibald Douglas Reid, King's College, London; George John Edward Pitman and Charlie Martin Row, University College, London; Thomas Gerald Fenton, St. Thomas's Hospital; Clement Arthur Douglas Bryan and William Murray Thomas, Guy's Hospital; John Richard Griffith, London Hospital; Arthur Herbert Foster and Arthur John Watson, St. Mary's Hospital; and Ridley Ewart Mounsey, St. George's Hospital.

Eighteen gentlemen were referred in both subjects.

Wednesday, Jan. 13th:

Anatomy and Physiology.—Charles Bernard Sells, Charles Edwards, John Brocas Chambers Brockwell, Guy's Hospital; Hugh Caleb Holden, Guy's and Westminster Hospital; Charles Wynn Wirgman, Nigel Frampton Stallard, and Percy Taylor Humphrey Stedman, University College, London; Charles Vaughan White, St. Thomas's Hospital; George Melville Smith, St. Thomas's Hospital and Mr. Cooke's School of Anatomy and Physiology; Harry Thwaites and Alfred Jones, London Hospital; Edward Arthur Sanders, King's College, London; and Archibald Malcolm Macintosh and William Richard Power Goodwin, St. Mary's Hospital.

Anatomy only.—John Micklethwait, Firth College, Sheffield, and Mr. Cooke's School of Anatomy and Physiology.

Physiology only.—Frederick Aylmer Hort, Cambridge University, Middlesex Hospital, and Mr. Cooke's School of Anatomy and Physiology; and William Morgan James, Cambridge University and St. Bartholomew's Hospital.

Twenty-five gentlemen were referred in both subjects, two in Anatomy only, and one in Physiology only.

Thursday, Jan. 14th:

Anatomy and Physiology.—Edwyn Gaved Andrew, George Shorland, Albert Edward Cawston, and Remus William John Radley, Guy's Hospital; Walter Edward Cooper, University College, London; Codanda Alpacha Nanjapa, Madras Medical College and University College, London; John O'Hea and George Joseph Alexis Leclezio, St. Bartholomew's Hospital; George Harrison Orton, Cambridge University and St. Bartholomew's Hospital; Edward Wemyss Browne and Cyril Alfred Rankin Nitch, St. Thomas's Hospital; Robert Augustus Greenwood Penny, St. George's Hospital; Charles Edward Etheridge, Middlesex Hospital; John Scarborough Dudding and Frederick James Purcell Daly, London Hospital; Meredith Sedgwick Doubble, Charing-cross Hospital; and Walter Edward Turner, St. Mary's Hospital.

Anatomy only.—Arthur West Walker, Mason College, Birmingham, James Augustus Rooth, St. George's Hospital.

Physiology only.—Thomas Arthur King, Cambridge University and St. Thomas's Hospital.

Sixteen gentlemen were referred in both subjects, two in Anatomy only, and one in Physiology only.

FOREIGN UNIVERSITY INTELLIGENCE.—*Catania:* Dr. Antonio Carci has been appointed Professor of Materia Medica and Experimental Pharmacology.—*Freiburg:* Dr. Kiliani, of Munich, has been appointed Professor of Chemistry, in succession to Professor Eugen Baumann.—*Geneva:* Dr. Johanès Martin has been appointed Professor of Psychiatry in succession to Professor Olivet, who has resigned.—*Giessen:* Dr. R. Sommer has been appointed Professor of Psychiatry,—*Heidelberg:* Dr. Max Jordan has been appointed Extraordinary Professor of Surgery. The university is about to lose the services of Dr. Von Beck, who was only recently appointed Extraordinary Professor, as he has been placed in charge of the Carlsruhe Hospital.—*Munich:* Dr. Karl Seitz has been appointed Extraordinary Professor of Children's Diseases.—*Naples:* Dr. Giacinto Vetere and Dr. Carlo Parascandolo have qualified as *privat-docenten* of Operative Medicine and Surgical Pathology respectively.—*Palermo:* Dr. Giovanni Dotto has qualified as *privat-docent* of Psychiatry.—*Tübingen:* Dr. Dennig has been appointed Extraordinary Professor of Internal Medicine.—*Würzburg:* Dr. A. Hoffa has been appointed Extraordinary Professor of Surgery.—*Vienna:* Dr. H. Peters has been appointed *docent* of Midwifery and Gynæcology.—*Zürich:* Dr. W. Felix has been appointed Extraordinary Professor of Anatomy.

MEDICAL FACULTY OF UNIVERSITY COLLEGE, LIVERPOOL.—The following table shows the number of medical and dental students attending the various classes at University College, Liverpool. Those attending at the Royal Infirmary who have not registered with the Dean this session are not included:—

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentleman having previously passed the necessary examinations, and having now conformed to the by-laws and regulations, has been admitted a Member of the College:—Llewellyn William Roberts, M.B., Ch.B. Melb., Melbourne University and King's College Hospital.

NEW HOSPITAL FOR BEDFORDSHIRE.—At a meeting of the governors of the Bedford General Infirmary on the 14th inst. it was decided to commence to build a new county hospital at a cost of about £33,000. Towards the sum required £27,000 are already in hand, including two donations each of £5000 from the Duke of Bedford and Mr. Whitbread.

FOOTBALL CASUALTIES.—During a match between Frome (Somerset) and Leighside Wanderers, on the 14th inst., a player sustained a fracture of his leg.—On the same day, in a match, St. Helens' Butchers against Theatricals, a player fractured his left humerus.—On the 16th inst., at Castletown, Isle of Man, during a match between King William's College Old Boys and Castletown, a Castletown forward fractured his leg, and another player sprained his ankle.

THE SLAUGHTER-HOUSE QUESTION.—The President of the Board of Agriculture will receive a joint deputation of the Church Society for the Promotion of Kindness to Animals and the Church Sanitary Association asking for further legislation respecting slaughter-houses on Feb. 25th. The Duke of Westminster will head the deputation. Copies of the memorial, which has already been signed by nearly 4000 persons, can be had on application to Mr. W. P. Gledhill, Church House, Westminster, S.W.

PORTSMOUTH MEDICAL UNION.—Mr. Gordon Sparrow, Mr. Emmett, Mr. McGregor, Dr. Sheahan, Mr. Norris, Mr. Malpas, Mr. J. E. P. Sparrow, and Mr. Gaston are each to be presented with an engraving of Mr. Luke Fildes's well-known picture, "The Doctor," as an acknowledgment by the profession of Portsmouth of the united stand they made with the assistance and advice of the Portsmouth Medical Union on behalf of the whole profession in the recent dispute with the Ancient Order of Rechabites. The presentation will be made by Dr. Ward Cousins at the rooms of the Medical Library on Tuesday next, Jan. 26th. A social and musical entertainment has been arranged to commence at 9 P.M.

SOCIETY FOR THE RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of the directors of this society was held on Jan. 13th at 11, Chandos-street. The chair was taken, in the unavoidable absence of the President, Sir James Paget, by Mr. Christopher Heath, Vice-president. One new member was elected and the deaths of one honorary and two other members were announced. It was resolved to distribute £1212 10*s.* among the fifty-one widows, thirteen orphans, and five recipients from the Copeland Fund. There were no fresh applications for relief. A present amounting to £368 had been given on Dec. 21st, 1896, among the widows and orphans on the books. The expenses of the quarter were £76.

BIRKENHEAD MEDICAL SOCIETY.—At a meeting of this society held on Jan. 15th, Dr. Sidney Marsden (President), being in the chair, Mr. H. Laird Pearson showed the Bone Handle of a Pen-holder four inches in length which he had extracted from the bladder of a middle-aged married woman thirty-six hours after its introduction. Under anæsthesia after dilating the urethra with Duke's uterine dilator the foreign body was after much manipulation extracted by means of a fine sequestrum forceps. There was no subsequent cystitis, and at the end of three days micturition, although painful, was well under control.—Mr. Stansfield, Dr. Brien, and Dr. Hughes made remarks and referred to cases of foreign body in the bladder.—Mr. C. Thurstan Holland of Liverpool gave an interesting demonstration of the uses of the Roentgen rays, first showing and describing the apparatus, enumerating several of the theories connected with the production of the rays, and then exhibiting a long series of lantern slides illustrating various physiological and pathological conditions of the skeleton as demonstrated by the rays.—A short discussion ensued, in which Dr. Harris, Mr. Stansfield and Mr. Wilkinson took part.

Hosted by Google

FREEMASONRY.—The York Lodge.—At the regular monthly meeting of the York Lodge No. 236, held at the Masonic Hall, Duncombe-place, York, on Monday, Jan. 18th, Bro. F. Sidney Gramshaw, M.D. St. And., was duly installed W.M. The banquet, held the same evening at the Royal Station Hotel, was largely attended, and an enjoyable evening was spent.

THE annual meeting of the Worcestershire Medical Society was held in the Library of the Worcester General Infirmary on Jan. 12th. Mr. T. Bates was elected president, and Dr. Stanley L. Haynes of Malvern, vice-president. Twenty-six new members were elected. A short paper was read by Dr. Swete on the History of the Worcestershire Medical Society. Cases were shown by Mr. Bates, Mr. Budd, Mr. Gostling, and Dr. Pollard.

A NOTABLE EXAMPLE.—A praiseworthy instance of consideration for the public service is reported from Southampton. Mr. H. H. Emanuel, to whom the Corporation owed £52 10*s.* as rent of premises which he owns, wrote desiring that the sum might be paid to the Royal South Hants Infirmary, the object being to qualify the medical officer of the county borough for the time being, as a life governor of that institution on behalf of the Corporation.

THE LARYNGOLOGICAL SOCIETY OF LONDON.—At the fifth annual meeting of this society, held on Jan. 13th at 20, Hanover-square, the following gentlemen were elected officers for the ensuing year:—President: Mr. Butlin. Vice-Presidents: Mr. Cresswell Baber, Dr. Bond, Dr. Bronner, Dr. Scanes Spicer, and Mr. Charters Symonds. Treasurer: Mr. Walsham. Librarian: Dr. Clifford Beale. Secretaries: Dr. St. Clair Thomson and Dr. Herbert Tilley. Council: Dr. Ball, Dr. McKenzie Johnston, Dr. Semon, Mr. Stewart, and Dr. Watson Williams.

LIVERPOOL MEDICAL INSTITUTION.—At the annual meeting, held on Jan. 14th, the following list of office-bearers, Members of Council, &c, was adopted:—President: Richard Caton, M.D., F.R.C.P. Vice-presidents: Robert Jones, F.R.C.S. Edin., *Charles H. Shears, M.R.C.S., K. A. Grossman, F.R.C.S. Edin., and *A. C. E. Harris, M.D. Hon. Treasurer: *James Armstrong, M.D. Hon. General Secretary: R. S. Archer, M.D. Hon. Secretary to Ordinary Meetings: T. B. Grimsdale, M.B. Hon. Librarian: *T. R. Bradshaw, M.D. Council: J. H. Abram, M.D., Hugh E. Jones, M.R.C.S., C. J. MacAlister, M.D, R. Robertson, M.D., *A. Stookes, M.D., *A. Bernard, M.B., *C. T. Holland, L.R.C.P., *T. D. Leigh, M.R.C.S., *L. Morgan, M.D., *G. P. Newbolt, F.R.C.S., *Mr. W. Permewan, F.R.C.S., *R. J. Richardson, M.D. Pathological and Microscopical Committee: Robert Boyce, M.D., J. H. Abram, M.D., W. T. Thomas, F.R.C.S., Frank T. Paul, F.R.C.S., A. W. Campbell, M.D., F. C. Larkin, F.R.C.S., F. H. Barendt, M.D., *R. A. Bickersteth, F.R.C.S., *C. S. Sherrington, F.R.S., and J. Wiglesworth, M.D. Those marked (*) did not hold the same office last year.

DIPHTHERIA IN LONDON.—The closing period of the past registration year consisted of five instead of the customary four weeks. But this circumstance does not render the facts incomparable, as the weekly averages can be considered. The December period of five weeks shows a total of 1442 notified cases of diphtheria in the county of London, against 1160 in the November period of four weeks. In December, the weekly average of notifications was 288, or only 2 less than in November. In December four districts had an aggregate of 432 cases, as compared with five having 416 in the preceding month. All the sanitary districts were invaded by the disease in each of the periods, whilst in the later month the Port of London was also visited by the malady on ship-board to the number of 6 cases. In December there were registered 257 deaths, yielding a weekly average of 51, as opposed to a weekly average in November of 55; and the per case mortality per cent. in the month just named of 19·0 gave place to one of 17·8 in December. There was, therefore, a like amount of disease in the two periods, with a mortality rate on amount of sickness in favour of the closing weeks of the year. Taking the whole year with its fifty-three weeks for purposes of registration, there were 14,224 notified cases, as against 11,426 in the fifty-two weeks of 1895, totals which yield for 1895 and 1896 weekly averages of 220 and 268 respectively. In Camberwell the 912 notifications in the earlier year gave place to 1447, and the 612 in Islington to 1152. The heaviest periods in 1896 were September and October and the lightest were April and January, and in the preceding year the periods were almost identical. Last week the deaths in London from the disease numbered 52, following on 71, but even so they were 17 in excess of the corrected decennial average for the first week of the period 1884–96. Poplar is credited with 6 of the deaths, Shoreditch with 5, and Islington, Hackney, and Bermondsey each with 4 deaths. Of the whole, 48 were those of persons aged from one to twenty years. The admissions to hospital in the week were 108, and last Saturday found 862 patients still under treatment. In the outer ring there were registered 6 deaths, in Kingston, Willesden, Hendon, Leyton (2), and Ilford respectively.

METROPOLITAN HOSPITAL SUNDAY FUND.—A meeting of the council of the Metropolitan Hospital Sunday Fund was held on Jan. 14th in the Venetian Parlour of the Mansion House, the Bishop of Stepney presiding in the absence of the Lord Mayor. Among those present were Archdeacon Sinclair, the Chief Rabbi, Canon Fleming, Lord Stamford, the Hon. Sydney Holland, Sir George Bruce, Sir Savile Crossley. Dr. Hare, Mr. Bloxam, F.R.C.S., Mr. Wakley, F.R.C.S., Mr. Willett, F.R.C.S., Rev. Dr. Marks, and Mr. H. C. Burdett. Letters of regret on account of inability to attend the meeting were received from Cardinal Vaughan, Canon Graham, the vicar of Islington, and others. The business to be transacted was the election of council, committees, and officers for 1897. The council for 1896 was re-elected, with the substitution of Lord Cathcart for Lord Knutsford, Mr. George Drummond for Alderman Sir Stuart Knill, Bart., and the Rev. Mr. Brock (Camden-town) for the Rev. J. Baillie. For the remaining vacancy, caused by the death of Mr. Joseph Fry, two candidates were proposed, and in the result Mr. A. S. Fripp was elected. Sir Stuart Knill and Mr. R. Grey were appointed as members of the committee of distribution to succeed Alderman Sir David Evans and Mr. H. Cosmo Bonsor respectively. Some conversation took place as to the expediency of proposing candidates whose consent was not formally signified. The honorary secretaries (Sir E. H. Currie and Mr. R. B. Martin, M.P.), the auditors, and the secretary (Mr. Custance) were re-elected, after which the proceedings terminated.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Opening of the Session.

THE third session of the present Parliament was opened by Royal Commission on Tuesday, Jan. 19th, the opening proceedings being attended by a large gathering of the Members of the two Houses.

The Queen's Speech.

The Queen's Speech delivered at the opening of the session refers to various matters at home and abroad which have occurred since the prorogation of Parliament five months ago. With regard to the famine in India, it says that the Indian Government are making every effort to mitigate suffering and to lessen the calamity, and that the development of railways and irrigation works and the forethought given through a long series of years to the preparation of the most effective arrangements for alleviating distress caused by famine make their task more hopeful than in previous visitations. Plague, the Speech goes on to say, has also made its appearance in the seaport towns of Bombay and Karachi, and, notwithstanding the precautions adopted by the local authorities, shows no signs of decrease. Directions, however, have been given to the Government to take the most stringent measures at their disposal for the eradication of the pestilence. Among the legislative proposals mentioned in the Speech are Bills to improve the arrangements for water-supply in London and to establish reformatories for inebriates.

Public Health Law in Scotland.

The Government has arranged to introduce in the House of Commons the Bill for the Consolidation of the Law as to Public Health in Scotland, which last session passed through the House of Lords after being considered by a Select Committee.

The Vaccination Question.

There is no reference to this question in the Queen's Speech, but it is understood that the Government are considering it and will come to a decision as to the legislation to be proposed when it has had an opportunity of examining Dr. Thorne Thorne's report as to the state of things in the continental countries he has just visited.

SOCIETIES.

MONDAY (25th).—MEDICAL SOCIETY OF LONDON.—8.30 P.M. Mr. H. Cripps: Three Cases of Intestinal Anastomosis, two of them involving Double Resection.—Mr. S. Bishop: New Operation for Vesico-Vaginal Fistula.

TUESDAY (26th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Dr. Lauder Brunton and Mr. A. A. Bowlby: A Case of Perforating Typhoid Ulcer treated by Operation and Suture and resulting in Recovery.—Dr. W. P. Herringham and Mr. A. A. Bowlby: Typhoid Fever Convalescence, Symptoms of Perforation, Laparotomy, no lesion found, Recovery.—Mr. F. Hawkins: Perforation of the Gall-bladder in Typhoid Fever.

WEDNESDAY (27th).—DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (20, Hanover-square, W.)—5 P.M. Dr. Pye-Smith: Varicella Bullosa.—Dr. Stowers: The Antecedent of, and Sequel to, a Case of Paget's Disease of the Nipple.—Dr. Abraham: (1) Extensive Epithelioma of Abdominal Wall; (2) Lichen Scrofulosorum (?).—Mr. Bidwell: Epithelioma of Leg. Cases by the President and others.

HUNTERIAN SOCIETY (London Institution, Finsbury-circus).—8.30 P.M. Mr. A. H. Tubby: Sprains and their Treatment.—Mr. Openshaw: Treatment of Pelvic Cellulitis.—Dr. Levy: Drawings from a Case of Pneumothorax.

THURSDAY (28th).—OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11, Chandos-st., Cavendish-sq., W.).—8 P.M. Card Specimens by Mr. Macnaughton-Jones, Mr. W. Dodd, and others. 8.30 P.M. Papers:—Dr. R. L. Knaggs: A Case of Spontaneous Recovery of a Retinal Detachment.—Dr. A. Robertson: Note on the Further History of a reported Case of Filaria Loa.—Mr. A. Lawson: Cystic Tumour of the Orbit.—Dr. C. E. Shaw: Perforating Wound of the Eyeball followed by Optic Neuritis.

FRIDAY (29th).—BRITISH LARYNGOLOGICAL, RHINOLOGICAL AND OTOLOGICAL ASSOCIATION (Medical Society's Rooms, 11, Chandos-street.)—3 P.M. Cases by Mr. M. Collier, Mr. F. Marsh, Mr. Lennox Browne, Mr. W. Wingrave, and Dr. Sandford 4.45 P.M. Adjourned Discussion on Dr. H. Campbell's paper, Breathing in Singers.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

TUESDAY (26th).—CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL.—4 P.M. Dr. D. Grant: The Details of Aural Therapeutics (Manipulations, Minor Operations, &c.).

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Dr. Ormerod: Lecture.

WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM (73, Welbeck-street).—Dr. H. Campbell: On Cases of Hemeplagia.

WEDNESDAY (27th).—WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.)—5 P.M. Dr. S. Taylor: Urine Testing.

THURSDAY (28th).—HOSPITAL FOR CONSUMPTION, &c., (Brompton).—4 P.M. Dr. Barlow: Demonstration.

FRIDAY (29th).—CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL.—4 P.M. Mr. Lennox Browne: Tuberculosis.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Dr. Tooth: Anatomy of Cranial Nerves.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index for the second volume of 1896 was given in the issue of Dec. 26th last. The practice of supplying loose copies has been discontinued, the Index having been placed in the centre of the journal, whence it can easily be detached, and placed either at the beginning or at the end of the volume.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1896 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.* (Local bookbinders will charge about 1*s.* for binding the numbers in these cases.)

To be obtained on application to the Manager, accompanied by remittance.

Young Practitioner will not be well advised to attempt to take proceedings. There can be no doubt that from his statement of the case he has a legal claim, but the damage he has suffered is a small one, and to get the reputation of being a man given to take offence early in his career will not stand him in good stead.

THE RUSH MEMORIAL.

A MOVEMENT is on foot in America to collect funds in order to erect a fitting monument to the memory of Benjamin Rush in Washington. The organisers of this appeal appear to a certain extent to be roused to their present efforts to do honour to Rush by the remarkable success of the homœopaths of America in collecting the sum of $75,000 towards erecting a monument to Hahnemann, and it is rightly contended that it will be to the shame of the regular practitioners of the States if they, outnumbering the entire body of homœopaths by more than 100,000, should allow their gifted and patriotic countryman to be commemorated by an insignificant bust or statue. Rush has peculiar claims on his countrymen; he has claims to their admiration and respect as a great physician, but his memory should be also venerated and loved as a distinguished patriot. As a physician Rush was one of the most noted men of his time; he was a voluminous writer in many branches of literature—of his purely professional writings Medical Enquiries and Observations are the best known—and he was perhaps the first authority on the "epidemic of fevers" of his day. But as a patriot he appeals to all classes and should live in the hearts of his countrymen for ever. He was a great friend of Franklin and was one of the signers of the Declaration of Independence. We believe that the Americans will not forget his services, but will heartily subscribe a sum sufficient to do ample honour to his memory.

THE ORGANISATION OF PROVIDENT DISPENSARIES BY THE PROFESSION.

To the Editors of THE LANCET.

SIRS,—The medical practitioners in towns where friendly societies have recently started institutes rather than adopt a wage or class limit have been strongly advised to organise provident dispensaries in opposition; but there are weighty objections to such a plan, two of which I venture to point out. First, it would be practically impossible for the local practitioners to exclude their supporters in the recent club battles. Amongst these supporters would be found those who have had, and will have, most illnesses; the club members who are never ill and do not know the old surgeon, being the friends of the money-saving institute. The consequence of this would be that the institute would be eased of the bulk of its responsibility by the provident dispensary. Secondly, the provident dispensary would have to be "pushed" to make it successful, with the result of an increase of cheap "contract work" in the town, and a corresponding diminution of regular private practice.

What is obviously wanted is a medical club which will attract young men of the working class, their wants being, firstly, medical attendance at a cheap rate, say 1*d.* a week; secondly, a sick-pay of from 10*s.* to 12*s.* a week during illness for a weekly subscription of about 5*d.*; thirdly, security that the system offering these advantages will last their lifetime or requirements; and fourthly, that a member changing his residence to another town shall have a reasonably good chance of finding a branch of his club, through which he could continue to reap the same advantages.

These are the main attractions offered by Oddfellows and Foresters, and as these societies pay it seems possible that the medical practitioners of the whole country could, either by themselves or in connexion with an insurance society, organise such a club, with the great extra advantage of giving each man his choice of medical attendant. As a member of a local sub-committee appointed to consider the advisability of starting a provident dispensary. I am sure that advice or help in any form on this point would be very welcome from you or any of your readers. Personally, I am convinced that this is the only method of successfully meeting the undisguised antagonism of the old friendly societies to the profession.

I am, Sirs, yours faithfully,

Jan. 15th, 1897. BETA.

METRICAL MEDICINE.

THE first number of the *Guyoscope* has reached us. Our new contemporary does not put itself into competition with the *Guy's Hospital Gazette*, but desires to supplement that record of serious work and effort by chronicling the ephemeral humours of the hospital. The editor has happened on a clever young artist in "Little Billee," and some of the reading is good. We extract the following stanzas concerning the feeding of babies:—

CANTO VI.

"Mixed milk is risky, for on it result you can't rely,
One cow, a well-fed healthy cow, should yield the whole supply;
Dilute with barley water, take equal parts at first,
And add a little sugar, don't let the baby thirst;
And as it thrives, and older grows, in manner as it oughter,
Increase the milk and sugar, and reduce the barley water.

CANTO IX.

"In giving meat, or, better still, meat juice, or broth, or tea,
Don't over-feed, one meal a day is wiser far than three;
At eighteen months the child may have a little solid meat,
Wine, spirits, beer, cheese, pastry, pork, the baby should not eat;
The swallowing of unchewed food must cause you constant fear,
Full very many British babes have died of diarrhœa."

A MEDICAL ENCYCLOPÆDIST.

AMONG the noteworthy *savants* and men of letters who succumbed during 1896 there were few, probably, whose attainments were more varied than those of Dr. Ernest Faligan, who was a native of Anjou, but ended his days at Ostend. Bachelor of Laws, Doctor of Philosophy, and Doctor of Medicine—possessing, in fact, but one degree, or rather licence, less than the distinguished *savant* Alglave—the deceased encyclopædist was likewise an ardent student of history, the classics, and modern languages. His thesis for the degree of Doctor of Philosophy was divided into two parts: the first, written in French, bore the somewhat ambitious title, "La légende de Faust chez tous les peuples et dans tous les siècles"; while the second, which was in Latin, was simply superscribed "Marlowe." Both these dissertations were sustained by the author at the age of fifty-five years. Dr. Faligan was also responsible for sundry romances, of which one called "The Corpse of the White House" was published in *Le Soleil*, as well as for a vast number of press articles on history, philosophy, and finance. He had but one defect, says the writer of an obituary notice in a Parisian medical journal—he was mad! An example of the pernicious effects of over-study and a warning to all geniuses with yearnings after encyclopædic fame.

THE SWALLOWING OF LEAD PELLETS.

To the Editors of THE LANCET.

SIRS,—In conversation the other day with a patient who was formerly in business as a gunsmith he told me a fact which may explain some obscure cases of saturnine poisoning. He said that he had at least a score of regular customers who were in the habit of purchasing half pounds of shot. On asking why they wanted it the answer was that it was for the purpose of keeping the lights down when they came into the throat. Some of them bought the largest shot made in the towers, while others thought that distributing the weight by taking three or four pellets was more effectual. Apparently the time occupied in the consumption of this quantity varied from one to three months. Most of them were women, who all declared that swallowing these pellets did them a great deal of good.

I am, Sirs, yours faithfully,

Burton-on-Trent, Jan. 18th, 1897. PHILIP B. MASON.

THE DEGRADATION OF THE PROFESSION.

"Is there nothing that can be done to prevent such a great lowering of our grand profession?" writes a correspondent, who encloses the following handbill:—

LLANHILLETH WORKMEN'S

DOCTOR'S QUESTION.

The Benefits derived by the Workmen by Paying

THREEPENCE

IN THE POUND.

1. A Resident Doctor in Crumlin, and Surgery twice a day there, instead of once as at present.
2. To attend to Confinements Free.
3. Veneral (*sic*) Diseases attended to Free.
4. Examinations Free.
5. Certificates for Clubs Free.
6. School Certificates when necessary.
7. Supply of Salts, Senna, Pills, Plaisters, Castor Oil, Bandages, Splints, and Teeth Drawing.
8. Cod Liver Oil.

REHABILITATION BY SHOCK.

CASES are on record of the instantaneous restitution of lost power, chiefly functional, or of recovery from maladies under the influence of sudden and strongly determined emotion; but we doubt if the recent annals of medicine offer a more striking illustration of the phenomenon than that just reported to us, on professional authority, from Italian Switzerland. At Osogna, in the Canton Ticino, an Italian, Luigi Dellosta by name, aged forty-one years, employed in the famous granite quarries of Jemetti and Caretti, had the misfortune five years ago to fall ill of a grave disease from which he emerged with total loss of speech and hearing—a perfect example of the deaf-mute. The other day business took him to the Ticinese capital, Bellinzona, and on his return in the evening he elected to go on foot to Castione, there to catch the train to Osogna. When on the road just where the bridge crosses the Moesa he saw a horse bearing down on him at a wild gallop. He had barely time, with a desperate leap and a cry of terror, to save himself from being knocked down, and a minute afterwards began to breathe freely. The shock due to the approaching danger and his effort to evade it saved him in more senses than one. He got back his speech and hearing, not, we hope, to lose them again.

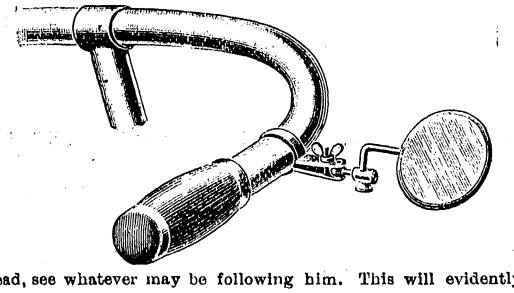
THE PLAGUE AND NAPOLEON BONAPARTE'S PREVENTIVE MEASURES.

"IT is interesting," says the *Pioneer Mail*, "to have a decided opinion on the much-vexed question of the contagiousness of the bubonic plague from so acute an observer as the Great Napoleon. His view is given in a curious little book published in 1816 by a Dr. Warden, the surgeon of H.M.S. *Northumberland*, which had conveyed the illustrious exile to St. Helena. It will be remembered that plague of a virulent type broke out amongst the French troops engaged in besieging St. Jean d'Acre in 1799, and that General Bonaparte, as the future Emperor then was called, showed an indefatigable zeal in visiting and consoling the sick. He told Dr. Warden one day that he was convinced that the plague could be communicated only through the organs of respiration; and on the medico saying that he had always understood the disease to be a contagious one Napoleon said, 'No; I visited the hospitals constantly and touched the bodies of the sick in order to give confidence to the attendants, being convinced that the disease can be contracted only through the lungs. At the same time I always took the precaution of visiting the hospitals after a meal and a few glasses of wine and of placing myself on the side of the infected person from which the wind was blowing.'" Our contemporary concludes by endorsing to some extent the great soldier's view. This we cannot do, but we can admire the energy and courage of the man in visiting the sick and trying to find out what might do good in the future.

Primary Exam.—Our Students' Number contains a list of the best books to read upon anatomy and physiology. Quain and Foster are indispensable to most students, and they can be supplemented in different directions if necessary.

"FAME OR ILL-FAME?"

To the Editors of THE LANCET.



SIRS,—Yesterday morning I woke to find myself on the point of becoming famous. It happened thus: The post brought me a flattering invitation from a well-known firm of photographers to sit for my portrait (free, gratis, and for nothing) that it might be added to a list of members of the medical profession. As I am on what is commonly called the sunny side of forty, and my career in medicine so far has not been noted for any achievement unusually good or bad, I was at a loss to know why my face should appear among those already to be found in the Gallery of the Immortals. Being one of those who think that the orchestra of modern London life is too noisy in the brass I blushingly declined the proffered honour. Who will now deny that we live in glorious times?

I am, Sirs, your obedient servant,

Jan. 13th, 1897. WEST-END.

THE "ARGUS" RETROSCOPE.

THIS ingenious device, due to the inventive talent of Surgeon-Captain Cockerill, consists of a diminishing mirror framed and supported in such a way as to be readily attached to the handle of a bicycle, so that the rider by merely looking into the mirror can, without turning his

head, see whatever may be following him. This will evidently be a great convenience and advantage to bicyclists, and perhaps in even a more marked degree to boating men. The irksomeness of constantly looking ahead will be acknowledged by most scullers, and yet it is just for them that vigilance is necessary on account of the length and instability of an outrigger. The makers of the retroscope are Messrs. R. Field and Co., 142, Suffolk-street, Birmingham.

A Suffering Schoolmaster.—That children's parties may play their part in the dissemination of disease we do not doubt, but to put any embargo upon them of the sort our correspondent suggests would be wrong.

CAKES UNDER THE X RAYS.

THE *Pall Mall Gazette* says:—"A novel use of x rays has transpired in Sunderland. A lady last week, while baking some cakes, lost her ring in the paste, but did not discover the loss until the cakes were out of the oven. Afraid of choking some member of her family she struck on the happy expedient of taking the cakes to a chemist and photographer, who placed them under the x rays, with the result that the ring was immediately located."

DEATH OF A DUBLIN CLERGYMAN BY POISONING.

ON Nov. 21st, 1896, our Dublin correspondent gave an account of the death of a clergyman in that city from accidental poisoning with "Wallace's Specific No. 1," the verdict returned by the jury at the inquest being as follows: "We find that the said Rev. Wm. J. Warren Boyde, LL.B., died on the 11th inst. at 60, Amiens-street, and that the cause of his death was cardiac syncope, produced by a poisonous dose of some preparation of aconite which he had taken about two and a half hours previously by misadventure from a bottle given to him by a friend, Mr. McGuinness, and procured for money by the latter from the address on the said bottle—viz., 4, Albany-terrace, London, N.W.—and bearing the name of 'Wallace's Specific No. 1.' We most strongly condemn the selling of a poison so deadly without being properly labeled and without the purchaser being properly cautioned as to its nature. We also desire to express the hope that the authorities may deal as stringently as the law permits with the vendor of the said poison." We have now received a copy of the *Herald of Health*, published during the current month, and containing the answer of the vendor of the nostrum. The answer is to the effect that the verdict was wrong, that "Mr. Wallace's aconite is comparatively innoxious," and that the death of the unfortunate clergyman was in all probability due to the emetics which were administered. The same paper also contains the remarkable statements—(1) that "Mr. Wallace in years past had both the time and the money to enable him to qualify if he chose, but his contempt for the secret oath and the unscientific position of the medical colleges was such that though constantly pressed to do so he persistently refused," and (2) that the fact of his not being qualified makes him more careful.

AN AMERICAN METHOD OF DEALING WITH MEDICAL AID ASSOCIATIONS.

THE following is extracted from the *New York Medical Record* of Dec. 19th, 1896, and is headed

"NO MORE LODGE WORK.

"The following significant resolutions have been adopted and signed by the physicians of Santa Clara County, Cal.:

"'*Whereas*, Rendering professional services at a stipulated fee per capita per annum is derogatory to the dignity of the medical profession, we, the undersigned physicians and surgeons of Santa Clara County, Cal., enter into the following agreement:

"'First, we mutually, jointly, and individually pledge our word of honour not to enter into any contract or agreement, or renew any existing contract or agreement, either written, verbal, or implied, to render medical or surgical services to any lodge, society, association, or organisation.

"'Second, we will not render medical or surgical services to the members of the above-mentioned bodies for less compensation than we charge the general public for similar services.

"'Third, this agreement shall not be construed to affect existing contracts between physicians and surgeons and the above-mentioned bodies.

"'Fourth, these pledges shall take effect and be in force for a term of three years from and after May 22, 1896.

"'This agreement shall not apply to hospitals and purely public charitable institutions.'"

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Hastings News, Halifax Guardian, Goole Times, Tyrone Constitution, Scottish Highlander, Forres Gazette, Falkirk Herald, Bradford Observer, Manchester Guardian, Scotsman, Newcastle Chronicle, Clifton Chronicle, Brixton Free Press, Hinckley Times, Faringdon Advertiser, Leytonstone Independent, Essex County Standard, Horsham Times, Western Morning News, Worcester Herald, Kent Messenger, Birmingham Mail, Eastbourne Chronicle, Craven Herald, Eastern Morning News, Sussex Daily News, Leicester Post, East Anglian Daily Times, Manchester Courier, Essex Telegraph, Kingston News, Liverpool Courier, Times of India, Pioneer Mail, Bristol Times, Builder, Leeds Mercury, Burton Chronicle, Hampshire Telegraph, Architect, Yorkshire Post, Poole Herald, Sheffield Independent, Bristol Mercury, Wolverhampton Chronicle, Liverpool Daily Post, Oldham Standard, Tonbridge Telegraph, East Grinstead Observer, Brighouse Echo, Sanitary Record, Hemel Hempstead Gazette, Cork Examiner, Galignani Messenger, City Press, Weekly Free Press and Aberdeen Herald, Hertforshire Mercury, Mining Journal, Reading Mercury, Local Government Chronicle, South Australian Register, Adelaide Advertiser, Surrey Advertiser, Blackpool Herald, Gazette News (Blackpool), Beckenham and Penge Advertiser, Tenby and County News, &c., &c.*

The Action and Uses of some New Synthetic Remedies.

DERMATOL.

SINCE the first communication on Dermatol, appearing in No. 24 of the *Berlin. Klin. Wochenschrift*, 1891, many reports on the new remedy have been published both at home and abroad. Further investigations in various directions seem to have established not only many of the early claims made for Dermatol, but have also indicated fresh fields of usefulness for it.

The physical characteristics of Dermatol are now well known. It is a fine yellow powder, unaltered by exposure to light and air, insoluble in ordinary re-agents, free from taste, and entirely without odour. The latter property is especially esteemed by patients on whom the employment of strong-smelling antiseptic powders like iodoform would entail serious inconvenience. The insolubility of Dermatol prevents its absorption, and it therefore never produces any toxic action whatever. Nearly all the writers in the medical journals remark specially upon the absolute freedom of the remedy from toxic properties, even when employed in large quantities under conditions most favourable for absorption.

A further characteristic of Dermatol is the absence of irritating properties. The unpleasant symptoms that sometimes follow the use of dressings such as iodoform, corrosive sublimate, &c., are never observed with Dermatol. Dr. Bluhm (*Therap. Monatshefte*) has tested its bactericidal power upon twelve different kinds of bacteria, comparing the results with those obtained from Iodoform, and finding the polyseptic action of Dermatol far superior to that of its repugnant predecessor.

It is more especially indicated as an absorbent, antiseptic powder for the treatment of fresh surgical wounds, slight accidental cuts, or old non-purulent wounds. When applied as a dusting powder it rapidly absorbs the secretions from wounds of these types, and forms a very hard, dense, and closely adherent crust, hence it proves extremely useful in all cases in which astringent and drying effects are desired. It has been reported valuable in crushed and lacerated non-septic wounds, burns, and scalds, and in large crural ulcers. Before the introduction of Dermatol it was impossible to close a sewn rectal or fistular wound with any degree of security. Now, this valuable chemical forms a protective crust in a short time, under which primary healing progresses.

In gynæcological practice it is attracting a great deal of attention, in view of the reports presented to the Bonn Gynæcological Congress. Remarkably satisfactory results were reported to have been obtained by its use in the treatment of laparotomy wounds, prevalent carcinomata, myomata, deep-seated tuberculous peritoneal abscess, and in infectious catarrhs of vagina, cervix, or endometrium. This report referred to, after calling attention to the superiority of Dermatol over iodoform, concludes: "Dermatol is absolutely unirritating, powerfully antiseptic, astringent, odourless, stable, and non-hygroscopic."

In dermatological practice it is highly recommended in the form of a 10 per cent. ointment with Lanoline for eczema in children, intertrigo mammæ, and intertrigo ani. It has been tried with excellent results as a dusting powder in dysidrosis of the hands and feet, in balanitis, in operations for phimosis, and, in alternation with antiseptic and stimulating remedies, in the treatment of bubo. For burns the 10 per cent. Lanoline ointment above mentioned is highly recommended.

Dermatol has been used with excellent results in otitis media suppurativa, otitis externa, and in a large number of cases of chronic middle-ear suppuration. The secretion was quickly reduced in quantity, and "most of the cases ceased suppuration after a few insufflations." In otitis externa it was employed (*Therap. Monatshefte*, 1892, No. 12) with excellent results. After two to five applications of the powder the aural cavity was dried, the swelling reduced, and the eczema healed. When used to check a purulent aural discharge, insufflations by means of a B., W. & Co. Powder Insufflator should be alternated with irrigations with an antiseptic solution, such as that made by dissolving a "Soloid" of Iodic-Hydrarg. in a pint of water.

In ophthalmic work it has been used in the after treatment of operations, and Dr. Werther reports successful results with Dermatol in phlyctanular inflammation of the conjunctiva in scrofulous children. It is an advantage that Dermatol can be employed for scrofulous patients simultaneously with potassium iodide, which is contra-indicated in conjunction with calomel.

Dermatol is supplied to the medical profession in 1 oz. tins at 1s. 2d. each. For the internal administration of Dermatol, "Tabloids" containing 4 gr. each are recommended as the most convenient form for administration, and are supplied to the medical profession in bottles of 24 and 100 at 8d. and 2s. each.

PHENOSALYL.

This is a clear, syrupy liquid, consisting of a mixture of Benzoic, Salicylic, and Carbolic Acids, melted together and dissolved in Lactic Acid. The results of all bacteriological trials with the mixture have shown that it possesses an antiseptic power considerably superior to that of carbolic acid. These trials dealt with the respective micro-organisms peculiar to the following diseases:—Cholera, Anthrax, Pneumonia, (Fraenkel), Typhus (Eberth), Diphtheria, Tuberculosis, and with Bacillus Pyocyaneus, and Staphylococcus Pyogenes Aureus. The results of these trials were completely satisfactory; even the last-named bacterium (which is the most resistant known) is immediately killed by a 1 per cent. solution, whilst to attain the same result with carbolic acid it is necessary to expose it to the action of a 2½ per cent. solution for at least one minute. A communication by Professor Fraenkel summarises the advantages of Phenosalyl over other antiseptics as follows: easy solubility in water; no danger of toxic symptoms; a pleasant and non-persistent odour which does not cling about the hands or clothes. Solutions of Phenosalyl have no corrosive action on the skin, the mucous surfaces remain smooth and slippery, and do not become dried up, as is the case after washing with carbolic acid or corrosive sublimate. Supplied to the medical profession in 2-oz. bottles at 10d. per bottle.

The above are produced by the Farbwerke vorm. Meister, Lucius, and Brüning, Hoechst-am-Main, and specimens may be had, as well as literature bearing on these and other new products, upon application to the agents,

SQUIRE'S CHEMICAL FOOD.

Known for 30 years as the best preparation of its kind

FOR DELICATE CHILDREN.

The Profession is cautioned against imitations, which differ in strength both from the original and one another in the most essential ingredients.

SYRUP OF SENNA.

A mild Aperient for Children, pleasant in flavour. Since its introduction, a quarter of a century ago, has been in continuously increasing demand.

CONFECTIO BELÆ RECENTIS.

A valuable remedy in Chronic Diarrhœa and Dysentery. Prepared in this country from Bael Fruits, Imported ripe and fresh in their Natural State.

DOSE—A Teaspoonful.

"It possesses all the aroma of the fruit, and is not only astringent where diarrhœa exists, but possesses the singular property of being aperient if the bowels be irregular or costive."

"Messrs. SQUIRE'S preparation is all that can be wished."—THE LANCET.

KASAK ELIXIR.

A Tonic Laxative — reliable, palatable, uniform in strength — without constipating reaction.

DOSE—For a Child, one or two Teaspoonfuls (according to age) at bedtime or in the early morning.

For an Adult, one Tablespoonful.

ALSO

KASAK PILULES. KASAK CAPSULES.

LIQUOR MORPHIÆ BIMECONATIS.

Syn.: LIQUOR MECONICUS.

A purified Solution of Opium with the Alkaloids in their natural state of combination, and standardised to contain 1 p.c. of Morphia.

NOTE.—The B.P. Solution, made by dissolving Morphia in Meconic Acid, differs very considerably from the above, and is no substitute for it.

LEHLIA.

The New and Admired Toilet Requisites.

LEHLIA Cream. Emollient for Face & Hands. 1s.

LEHLIA Dentifrice. A Perfect Tooth Powder. 1s.

LEHLIA Dusting Powder. For Nursery and Toilet. 1s.

LEHLIA Extract. For Use after Exposure to Sun or Cold Winds. 1s.

LEHLIA Soap. Pure and Refreshing. In boxes, containing 3 cakes, 2s.

An Address

UPON DIAGNOSIS OF TUMOUR OF THE CEREBELLUM.

Communicated to the Società Medico-Chirurgica of Bologna.

BY PROFESSOR AUGUSTO MURRI.

GENTLEMEN,—As from divers personal reasons our colleagues Boari, Cantalamessa, and Melotti cannot fulfil their promise, and the benefit of their instruction must be postponed to a future meeting, I have thought it well to substitute a discussion on the diagnosis of a case which I presented to my students yesterday. The patient has been scarcely four or five days in the clinic, but some colleagues at Ferrara who advised him to come here have sent with him historical data so well arranged that we must all appreciate their worth, and I myself have known them for many years as extremely clever men.

The patient is a young man, aged seventeen years, living at Ferrara. His father, now a man about forty-six years of age, is addicted to drinking, and from the time of the birth of our patient has been unable to work. He suffered then from a serious affection of the respiratory organs the precise nature of which his wife is unable to describe. From this he has partially recovered, except for a bad cough which upon any unusual exertion becomes so intense that he is obliged to remain in bed. The wife has always been very healthy and has borne twelve children, eight of whom died in childhood from inflammation of the intestines. Of the four still living, the two elder are in good health. One younger than they, however, has suffered ever since his childhood from epileptic fits. The patient, with the exception of measles, has never been ill, and grew up strong and active. In June, 1893, while playing ball, he suddenly became so giddy that he fell to the ground. There was no convulsion of any kind, and he did not lose consciousness; on the contrary he distinctly remembers replying to a companion, who was teasing him under the impression that he had thrown himself down for fun: "Leave me alone; I cannot stand on my feet." Notwithstanding, a little later he succeeded in rising and, accompanied by his friends, went home, where he did not even go to bed as he felt perfectly well again. From that day he was troubled by a slight headache, the exact seat and precise duration of which he could not determine; the giddiness returned and nausea and vomiting occurred, which he believed to have sometimes been caused by some indiscretion with regard to diet, but which at other times were independent of any digestive disturbance and manifested themselves especially at night. Sometimes vomiting accompanied the giddiness or occurred when the headache was at its worst, which was always towards evening. At that time he asserted that he had a singing in both ears, but only intermittently. He also observed that his right leg, especially in running, grew tired sooner than the left, and the household in general noticed from the first signs of the illness that he reeled in his walk. The mother said that his walk seemed especially uncertain on the right, whereas until then he had always been direct and quick. All this did not impede the patient in his work, but early in 1894 fresh disturbances evinced themselves. His mother recounted that about this time she began to notice that the boy no longer spoke clearly; in fact, she scolded him for speaking too fast and slurring over his words. The tone of voice did not appear to have been changed. It was also remarked that the lad had grown deaf in the left ear, but the beginning of this deafness cannot be determined, having been noticed casually. The patient himself had not observed it even when the singing in his ears had become more marked on one side. He never suffered any great pain in the left ear, and had never remarked any purulent flow from it, but he began to notice a diminution of hearing on the right side also. It cannot be decided whether it was at this time that facial paralysis began to show itself. The attacks of giddiness became more frequent (from three to four times a day), the headache grew worse, and the nausea and vomiting were more incessant. The patient was attacked with giddiness suddenly, but he was able to give warning of it to his companions, as his sight grew dim first and things appeared to swim round him. He would fall forward without losing consciousness, and could hear a person speaking to him, although sometimes he was unable to answer. He remained three or more minutes with his head bent forward, after which he recovered, remembering perfectly all that had happened during the attack. The headache grew worse, especially towards evening, and by the end of the spring it had become so intense that sometimes when returning from his work he could not walk and was obliged to stop or to walk slowly holding on to the wall, tottering more than usual. The headache was frontal, but it did not last more than from half to three-quarters of an hour. One evening (June 3rd, 1894) he returned home much indisposed, and being very tired he went to bed. When his mother entered the room she found him pale as a corpse, with his muscles in a state of complete relaxation—so much so that for a moment she thought he was dead. He had lost consciousness, and his mother called him in vain. He showed no kind of convulsive movement, but had rather the aspect of a person in a swoon. After half an hour he came to himself, felt his head clear, and rising, he descended to the street. Here, as was his custom, he commenced to smoke, but was attacked by vertigo so strongly that he nearly fell, and he was carried back to bed. A medical man was then called. He examined him and advised his entering the hospital at Ferrara. This he did on June 4th, remaining there till the 25th. During his stay there the following symptoms were noticed. There were paresis of all the left side of the face, slight rotatory nystagmus of the eyeballs, and a halting in the speech, without, however, missing any words. The dynamometer marked—right hand 52, left hand 60; the reflexes of the patella were slightly exaggerated, the pupillary ones normal; clonus of the foot was absent; there were no disturbances either of the bladder or rectum, no pain in the legs, and no loss of memory or other alterations of the mental qualities. At night he dreamed much, so that one night, in flying from some fancied peril, he fell out of bed and broke three teeth. The patient, having left the hospital at his own desire, was in July visited by two other practitioners, who ascertained, beside the above-mentioned phenomena, that pressure produced a pain in correspondence with the left temple and that there were a relaxation of the left side of the face and on the right an enlargement of the pons zygomaticus and temporal prominence. The back of the eye was examined and found to be turgid, the papillæ in the left being red. Finally, in August, 1894, the patient presented himself in the ambulatory of the madhouse of Ferrara. Nothing was noticed then excepting lesions of the nervous system, which were as follows. Total paresis of the left side of the face and atrophy of the muscles of expression on the same side, so that the right naso-labial sulcus was less arched than the left. In the left temporal region was a point which was painful upon pressure. On the left all the branches of the muscles above and beneath the orbit and in the jaw were painful on pressure. There were, also, entire deafness of the left ear and alteration of speech. The patient found especial difficulty in pronouncing words with many labials, but he neither paraphrased nor dropped words. The tongue was well projected, not deviating from the median line, and without tremor. The roof of the palate and position of the uvula were normal and there was a slight lateral nystagmus, sometimes rotatory, in the eye. The upper limbs on the left had a little less force than those on the right. On causing the patient to extend his arm a slight tremor was noticeable on the left, which was augmented when he wished to perform any delicate movement with his hand, such as taking up a needle; the right arm was normal. There was a distinct tottering in his walk; he threw his right leg outwards, especially in the act of putting it forward. When upright he threw all his weight on the right leg, but turned the shoulder of that side a little lower and towards the right. (His mother says that she has noticed this position in her son from the first days of his illness, and it appears that he keeps to this position as the one best adapted to maintain his equilibrium.) The patellar reflexes were a little exaggerated, all the others being normal. An examination of the general sensibility had a negative result, for it was perfect in all ways, tactile, thermal, and algesic. Sight and distinction of colours were good, and both smell and taste were normal. As to the explanation of his

Hosted by Google

uncertain walk the patient said he did not feel the ground but seemed to be walking on ice. On Nov. 20th, 1894, returning to the ward, an apparent improvement of the paresis of the face was noticed, while the muscles were in a state of complete repose. In mimic contractions, however, there was an evident deficiency of contractile force in the muscles on the left side, both in the upper and the lower part of the face. His speech was also clearer. The nystagmus was more noticeable, though the dilatation of the pupils was equal. Vertigo was more frequent, the headache and sickness had disappeared, and the intentional tremor of the left arm had become greater. The dynamometer was—right hand 60, left hand 45. His walk was still more tottering, but at the same time spasmodic. The patellar reflexes were much exaggerated and the superficial abdominal and cremasteric ones diminished. On Dec. 4th he presented the usual symptoms, but with graver characteristics. He had more difficulty in assuming an erect position, and his gait was increasingly unsteady and so spasmodic as to necessitate the use of a stick. The facial paresis seemed replaced by a state of contraction, for the angle of the lip was higher on the left side than on the right, as was also the arch of the left eyebrow, while the right muscles had greater power of contraction. The trembling of the extended arm was greater on the left, but was beginning also on the right. The patient complained of a slight headache of a new form which seemed to begin at the occiput and to extend to the forehead. It was especially frequent in the mornings, was not very intense, and disappeared after a short time. The pupils reacted slowly to light, the brain seemed all right, and memory and attention preserved. Perhaps there was a certain euphoria, because the patient was tranquil and often laughed, though he knew the gravity of the malady. Lately he has become much worse; he can no longer walk without a stick, and often leans on the arm of the person who accompanies him. The tremor has become noticeable in the upper limbs and has invaded the lower ones, especially on the left. If while lying in bed you make him lift his leg towards a certain point it shows a species of intentional tremor stronger on the right. In an upright position the body oscillates backwards and forwards, and laterally. When seated on the bed the patient presents the same oscillations and only finds his equilibrium in resting his body at the back and on the right. The tongue projects in the median line, but has longitudinal vermicular contractions chiefly at the edges. The patellar reflexes are still more exaggerated; there are a clonus of the rotula and notable plantar reflexes, but the cremasteric and abdominal ones are diminished. Negative results are obtained in examination of the sensibility, only the muscular sense is not quite exact, especially in the left arm. Sight is intact, but the patient says that the lines and letters run easily together. On a superficial examination the visual field seems restricted. On some days there is a distinct frequency and irregularity of cardiac pulsation. The breathing is usually abdominal, sometimes interrupted by sighs. Lately the patient has suffered much from hiccough, especially at night, and some days he has a noticeable diarrhœa. His temperature is normal. He affirms that he has never contracted venereal or syphilitic diseases, and has been always well-nourished. He has drunk a little to excess, consuming two litres of wine a day, but has not taken spirits. Smoking, which is habitual, brings on vertigo. The functions of the bladder have always been regular, but he has suffered from constipation of the bowels from the beginning of his malady. A certain loss of memory is noteworthy, he forgets many things described in history or which have been narrated by his mother.

OBJECTIVE EXAMINATION MADE IN THE CLINIC ON JAN. 28TH, 1895.

General characteristics.—The patient is of middle height, well formed, in very good state of nutriment. The skeleton is regular, and the muscles well-developed, only some small lymphatic glands, a little enlarged and indurated, were found in the right side of the neck.

Thorax and abdominal organs.—Nothing worthy of note results from the examination of the internal organs, except the first sound at the apex which is a little rough with a tendency to re-duplication. The pulse is between 90 and 95 a minute.

Nervous system.—He has power of movement. When the face is in a state of repose the arch of the left eyebrow is a little more raised and curved than the right; the fossa of the left eyelid is slightly narrower than the right; the left half of the upper lip is more arched than the right, the left naso-labial furrow being more marked than the right; the direction of the visual axis on the left has a slight convergence more marked than on the right. The left temporal region as well as the cheek is a little more depressed than the right one; while, on the contrary, the pons zygomaticus is more prominent, as is the temporal bone in the part above the pavilion of the ear. The muscles of the sterno-cleido-mastoideus are a little strained, especially on the right side. During the action of the muscles of expression the function of the frontalis is well preserved and almost uniform on both sides. The orbicular muscles of the eyelids also contract well on both sides, though perhaps there is a very slight predominance on the right. During a forcible closing of the eyelids the left angle of the lip is drawn up, and the left naso-labial furrow becomes deeper. This inequality of tension in the motor functions is more noticeable after some seconds if the voluntary contractions are continued, because the right muscles have a tendency to relax while those on the left side remain contracted. On being told to show his teeth, laugh, &c., there is seen at first a rather more vivacious action of the muscles on the right, but it soon gives place to the predominance of contraction on the left. The tongue is put out with a certain promptness and generally does not deviate, only sometimes a tendency to the right may be noticed, and it is liable to almost rhythmic movements which easily change its form and position. These involuntary movements are more often visible on the right half. The mucous membrane is smooth and thick, and on observing the tongue within the oral cavity it seems a little convex and more developed in the left half. In a state of repose the left arch of the palate is more arched and elevated than the right; during its function a slight augmentation of contraction may be noted in the left half of the back of the mouth. The function of the masticatory muscles is not equal on both sides, for during mastication the stiffening of the left masseter is less marked than on the right, and the same is the case with the temporal muscles. Also, in opening the mouth wide the upper jaw deviates slightly to the left, yet when fully open it goes back again to the median line. The lateral movements of the jaw are rather limited; however, it cannot be decided with any certainty which side predominates. The forced direction of the visual axes to the right is accomplished without difficulty, although there directly ensues a horizontal tremor of the eyeballs, which ceases when in repose. Voluntary direction of the pupils of the eyes to the left is less easy; besides, the pupils tend to turn slowly back, which produces a horizontal strabismus from right to left. The forced convergence of the visual axes is nearly normal. Sometimes when the sight is strongly directed to the left a slight secondary deviation of the right pupil may also be noted. In repose, and especially when the patient is seated, the head tends to fall a little backward on the right side. Wide and slow oscillations of the trunk take place when seated or standing, irregular oscillations, more often lateral, but at times backwards and forwards. Lateral motions, flexions, and extension of the head are easily accomplished, almost in normal fashion, but it can be perceived that the patient finds it easier to move the head to the right. Active and passive movements of the upper limbs, are made well enough as long as only energetic force and coarse movements are required. If a rather delicate and precise action has to be performed, a slight trembling or a state of incoördination may be observed, especially in the left arm. For example, when desired to touch the point of his nose with the tip of the first finger of the left hand before arriving at the nose he makes one or two oscillations, seemingly more the effect of a slight ataxia than an intentional tremor, for instead of touching the point indicated he touches more often some other spot near it. Being told to put a glass or spoon full of liquid to his mouth, he does so with his right hand without spilling a drop, while with the left he spills the liquid by reason of this same incoördinate motion. Desired to hold his hand and arm firm and extended, no tremor of any sort is visible, except now and then a slow irregular oscillation of the whole limb. Muscular force is well developed in the right arm and the flexion of the fingers as marked by the dynamometer 130 in the grand circle. In the left arm it is less developed, however, there is a certain energy of contraction, and the dynamometer marks 95 on the grand circle. The muscular sense of position of the arms is fairly preserved

Hosted by Google

and the muscular sense of force slightly weakened. In regard to the nutrition of the muscular masses a slight difference may be noted between one side and the other, for on the right the muscles are well developed, while on the left they are less so and have besides less tone. In fact, the right forearm at 7 centimetres beneath the olecranon measures 26 centimetres in circumference, the left 24. The right arm at 15 centimetres above the olecranon measures 26½ centimetres, the left 25½ centimetres. In the lower limbs the difference is less perceptible. The active movements of the legs are performed in a very irregular and abnormal manner, for when desired to touch a given spot with his foot while lying in bed the movement is made with distinct want of command, especially over the right leg. On the other hand, being told to touch his left knee with the right heel, he makes a rapid and exaggerated sudden motion that brings his foot half way up the thigh; then, with oscillations more or less wide but irregular, he seeks to reach the knee, on which at first he cannot hold his heel. This ataxy is less intense on the left. Also when desired to lift his legs up from the bed and extend them there were oscillations in all directions which increased curiously when the limbs were tired, which soon occurred. The force of flexion is tolerably well preserved in the lower limbs and with a sensible difference between one side and the other, for on the right the dynamometer shows 58 and on the left only 48 (in the sense of traction on the two poles of the dynamometer). The movements are normal everywhere; muscular sense of position is well preserved in the lower limbs.

Reflexes.—Superficial and plantar reflexes are present on both sides and the cremasteric ones the same. The abdominal reflexes are very evident on the right side and scarcely perceptible on the left. Direct muscular reflexes are well manifested everywhere. As regards the tendon-reflexes the patellar is much exaggerated on both sides—a little more, however, on the left; that of the tendon of Achilles is also very evident; that of the triceps brachialis is exaggerated on both sides, but more so on the left. Clonus of the patella is very evident and prompt on both sides, and clonus of the foot the same, with slight prevalence in the left. The facial reflexes are sensitive to pricking and much more visible on the left. The reflex of eyeballs is normal. The pupils for the most part are slightly dilated, but are of equal size and react well to accommodation. The nasal reflexes are scarcely perceptible. Reflex of the pharynx is nearly gone. Reflexes of the eyelids and cornea are normal on the right, but nearly gone on the left. The function of deglutition is normal; one may almost say the same of those of the bladder and anal reflexes.

Sensibility.—The thermal, algesic, and tactile sensibilities are nearly normal everywhere except in the left half of the face, which is insensible to touch in the frontal region, the left half of the nose, cheek, eye, ear, and orifices of the nose and mouth, as well as the left half of the tongue, palate, and the back of the mouth. This anæsthesia is more profound close to the left of the median line of the face, gradually diminishing on the parotid region and left temple, and eventually disappearing in the pavilion of the ear, and lower jaw. Thermic sensibility on the left half of the face is but slightly less acute than on the right. The sense of pain, on the contrary, is greater on the left than on the right, for even the firm pressure of the finger on the orifices of emergence of the fifth nerve of the left side, or upon the bones of the face, especially upon the zygomatic arch, causes a sense of pain which is not felt in the same regions on the right side.

Special senses.—The sense of sight is sufficiently preserved on the right, while it is slightly diminished on the left. An examination of the visual and chromatic area reveals no alterations worthy of special notice. An examination of the fundus of the left eye shows the papilla to be of a somewhat redder colour than usual, the circumpapillary retina of a grey and cloudy aspect, and the veins slightly dilated, the arteries presenting an ordinary appearance. In the right eye the margins of the disc are less distinct than in the left eye, the red colour exists as upon the left, a grey halo in the peripapillary retina is observed, and the condition of veins and arteries is not noticeably altered. The olfactory organs are normal and acute on the right but a little weakened on the left, and the patient complains of his nose being stopped up, a fact caused by the left nasal orifice not being perfectly free. The hearing is somewhat weak on the right, on which side he complains of an occasional singing in the ear. On the left hearing seems completely gone when tested by the ticking of a watch, for the sound remains unperceived either through the auricle or through the osseous labyrinth. Conversation can be heard on the right at a distance of more than 8 metres; on the left, on the contrary, only at a distance of about 30 centimetres. Singing on the right can be heard at 5 metres distance, on the left not at all. An otoscopic examination shows nothing abnormal on either side. In the roof of the pharynx, which appears almost normal, the left half of the Luschka tonsil shows depressions rather less deep with colour somewhat more vivid than on the right and seems to bulge a little, but the difference is so slight that Dr. Carlo Sacchi who made this part of the examination considers it of little importance in itself. On the left side of the tongue no differences of taste are observed except during the act of deglutition; on the right side also the sense of taste in general is somewhat obtuse.

Standing position.—He can stand on his feet without support and with eyes closed, but there is slight oscillation of the body towards the side, or more often backwards and forwards, and these oscillations increase somewhat when the eyes are closed. On the whole he tends to lean the weight of the body more upon the right leg. He cannot stand on one leg alone; not so much because strength lacks as because the oscillations increase so perceptibly that unless he were supported he would fall. His gait is composed of a mixture of three types: ataxic, spastic, and slightly zigzag. The ataxic character is more noticeable in the right leg. He cannot run, but still less can he walk slowly. The mental faculties are normal; only memory is slightly impaired. His speech is rather unintelligible, because, besides having a nasal tone, clear enunciation of words is very difficult to him and the syllables tend to run together, producing a language very hard to understand; yet some words are pronounced clearly and distinctly. Electrical examination only shows a slight augmentation of galvanic excitability of the muscles of the left side of the face in comparison with the right, but the difference is very slight.

Résumé from the case-book.—The patient was kept under observation in the clinic for five days, during which the following facts were noted. He had scarcely any headache; there was fugitive double vision; he had several attacks of vertigo, one of them a serious one during the discussion in the clinical amphitheatre. After having listened attentively for nearly an hour to the exposition and diagnosis of his disease the patient was attacked with confusion of ideas and sense of extreme giddiness; he became red in the face and had a hard cough, which increased the facial contortions on the left and slackened the pulse, which declined from 90 to 60, still keeping its rhythm. After two or three minutes it all passed away without his consciousness being at all obscured and without any gastric or aural disturbances. The morning of the next day while eating the patient had another nervous attack a little differing from his usual vertigo. His neighbour in the next bed saw him all at once become rigid, with his gaze fixed forwards with a tendency to the left; then the man jumped out of bed to hold him up, seeing he was unconscious and being afraid he would fall. He called and shook him, but he gave no signs of understanding. He did not become pale, but remained rigid for a minute with his muscles relaxed. Then the nurse noted a fugitive tonic spasm in both arms and he came to himself, saying he had a headache and remembered nothing that had happened. He recommenced his meal which had been interrupted and complained of nothing further. The visceral functions are intact; urine on examination proves normal. His temperature is always normal; his pulse beats from 90 to 94, is small, rhythmic, and equal; the respirations vary from 20 to 22 and are regular. The mental condition is good. The patient troubles himself but little about his serious condition. He asks for surgical treatment, from which he hopes either cure or death, which he does not fear.

What is the cause of all these disturbances? The medical man who first examined the patient made the diagnosis of sclerosis disseminated through the cerebro-spinal region; and, in fact, the strabismus, the altered pronunciation, disordered movements, trembling of tongue, age of patient, absence of disorder of the senses, and the multiplicity of symptoms would seem to indicate some wide and varied lesion. But on looking well into the case this likeness vanishes. The motorial disorder is not an intentional tremor, but rather an almost chorea-like movement. If the patient is told to put his finger to his nose or his left heel to his right knee his

Hosted by Google

arm or his leg do not tremble, but simply mistake the scope; he succeeds only after repeatedly bringing the finger or foot to the place. If the patient performs a motion with his hands or extends his arms before him the disordered movements are limited to the fingers; there is scarcely any of that trembling in the mass of the limb such as is to be seen in sclerosis. For this reason we have in vain attempted to take a tracing of the movement. The same is the case with the tongue; there is none of that subtle and uniform motion proper to sclerosis, but instead an instability of the tongue which without any rule turns here and there as in chorea. The broken speech is also different; here the syllables hastily succeed one another, are badly pronounced, and some entirely slurred, but there is none of that infantile articulation, that measured speech, which patients present in sclerosis. But even though the principal facts are thus wanting we have plenty of others. The insensibility to touch and hyper-sensibility to pain in the area supplied by the fifth nerves is decidedly unusual, the symptoms of Menière's disease — i.e., violent vertigo, subjective noises, and deafness—which here constituted the first disturbances and after twenty months still continue intensely, is also distinctly unusual. Nor are the paroxysms of accelerated, or of difficult action of the, heart more common. I fully understand that with any imaginary variation as regards locality, number, and extension (disseminated sclerosis not being under any definite laws), one might construct a clinical expression adaptable to our case. But this is not my method. Symptomatology cannot be drawn from anatomy; it is verified by observation. Now analysing the phenomena presented by our patient we find they do not correspond to those which observation has shown to belong to disseminated sclerosis, and therefore we must et aside this diagnosis.

The gait of our patient causes us at once to think of the cerebellum, but even here, looking well into the case, the phenomenon loses its value. The real tottering scarcely exists at all at this stage, though it may have been there at the beginning. Now it is evident that if the patient does not walk absolutely straightly it is chiefly because there are excessive muscular contractions in the limbs and trunk; his gait is a mixture of spasm and ataxia. Now he cannot lift his foot from the ground, then he throws it out in a nervous manner, not with the limb extended, though the foot is turned downwards and the knees bent. And this phenomenon is not confined to the lower limbs; when he is seated his head is at once turned backward and the body is rapidly drawn to one side, although the position must be a very strained one. There are, then, very different traits to those one expects in cerebral disturbance. Add to this that there is no functional disorder in the eye, no strained eyeballs, headache is rare and of short duration, nor is it intense unless it comes on when the patient is walking; the left arm is in a state of atrophy, all symptoms not belonging to tumour of the cerebellum, the only lesion of which we can think. In fact, the only true indication of disease of the suspected organ is the disorder of the movements, but even this is not typical. Indeed, this same phenomenon is noticed also when the tumour, instead of the cerebellar lobe, is located in the quadrigemina, the pons cerebelli, the peduncles of the cerebellum, or the bulb. The tendency towards diagnosis of tumour of the cerebellum, which medical men have whenever they see the ataxic walk, is not founded on good reasons empirically verified, but from the fact that the cerebellum being more often the seat of tumour than are the other parts I have mentioned, the opinion expressed most frequently proves to be the true one, though based on a weak argument.

If, judging from the present derangements, we opine that our patient's injury is in a part of the brain we should at once think of the "pons" or the bulb. In fact, lesions are indicated in the fifth, sixth, seventh, and eighth, probably the ninth, certainly the twelfth on the left, the eighth on the right, the nucleus of the sixth on the left, both the pyramidal tracts, and finally the centre for vomiting, the heart, the salivary secretions, and the bladder. All these innumerable disorders depend certainly on stimulation of the "pons," the bulb, and the floor of the fourth ventricle. Is the tumour, then, situated in this region? I say, without further preamble, tumour, because no one could dream of hæmorrhage or softening of the brain during the course of the malady, and the character of the symptoms is such that a suspicion of nuclear degeneration could not enter one's mind. Nevertheless, I do not believe even in a tumour of these parts, because a tumour which has existed twenty months in that zone must have destroyed some tissue, while, on the contrary, in this case nothing is destroyed. Very many of the functions which depend on that region are disordered, but none abolished. The fifth is insensible to touch, but is, on the other, sensible to pain; the sixth acts less, but the muscle of the rectus externus is innervated, the nucleus which innervates the left rectus externus and right rectus internus acts less effectually than usual, but nevertheless it does act; the seventh is almost normal and its nucleus acts tolerably well, because the nerves to the face muscles are well nourished and scarcely deteriorated and their reflex action well preserved. In short, the same may be said of all the rest. Now I cannot believe in a tumour invading a tissue where there are no latent zones; it develops and increases, as the constant augmentation of symptoms testifies, without abolishing any of the functions, which in a zone so restricted have their centre and paths of transmission. We cannot affirm that a fibre or a cell is wanting, therefore we cannot admit that for twenty months a tumour has exercised its destroying power in that zone.

What must we then conclude? That the pons and bulb are entire, but act badly. Why? Here lies the gist of the question. The morbid phenomena only tell us that innervation of the pons and bulb is impaired; on the other hand, it is impossible to believe that any devastating process whatever exists in these same parts. Hence nothing remain to us but this, that the pons and the bulb, though existing in all their parts, are in a changed physiological condition because they are compressed. And here is a new argument for the tumour, for a tumour can only compress from outside the medulla oblongata (or pons Varolii).

But where is the tumour? Notwithstanding the integrity of the fourth and of the third nerves the compression cannot come from the quadrigeminus; it must come from the base of the skull or the cerebellum. It is not from the base of the skull, because it is more inconceivable than ever how the seventh, being compressed and flattened for so long instead of being quite paralysed, has re-acquired a little of its lost power. Besides this it would be difficult to explain the absolute integrity of the spinal cord; while the hypoglossal, perhaps the glosso-pharyngeal, and probably the vagus nerves are impaired. Finally, the lesion of the fifth, if it were peripheral, before causing numbness would have caused neuralgia. Therefore, the improbabilities are such and so many that we may conscientiously exclude the hypothesis of a tumour arising from the base to compress the pons and medulla oblongata. At first the left zygomatic arch, being a little prominent and painful to pressure, had excited the suspicion that an osteo-sarcoma of the cranium had invaded the cavity; but on one side the rhinoscopic examination showed that no alteration referable to osseous neoplasm of twenty months' duration existed, and on the other side the pain upon pressure was found to depend on sensitiveness of the trigeminus. Knowing how frequently want of symmetry occurs in the two halves of the face we cannot assign too great weight to the greater protuberance of the left, the more so as the apparent enlargement of the zygomatic arch is brought into relief by the slight diminution of volume of the softer parts of the left side of the face.

As a consequence of these considerations we are confined to a diagnosis of a tumour situated in the left half of the cerebellum, comprising the left side of the pons and bulb. To be sure Oppenheim has recently written simplifying the diagnosis of tumours of the cerebellum, yet I maintain that although the supposition of one may be easy the demonstration is difficult. Here, however, the demonstration appears to me impossible, because all the other hypotheses clash against some symptom irreconcilable with them; the hypothesis of a tumour of the cerebellum is the only one which will agree with all the facts.

Yet in considering the foundation of this clinical interpretation of the phenomena presented by our patient one perceives that more assistance is obtainable from physiological and pathological anatomy than from experiment. Of the phenomena so acutely investigated by Luciani the asthenia and atony, as the dynamometric data show, are wanting; the youth develops a force which seems normal. It is true it is less in the left hand than the right, but, if you remember, the left arm is wasted. Besides the atony we have a remarkable excess of tone in all the limbs, and also in the muscles supplied by the seventh nerve on the left. But these facts are not irreconcilable with Luciani's observations,

Hosted by Google

since an experimental lesion which lasts twenty months is one thing and a neoplasm is another. The latter has, or may have, a permanent irritative power, and yet not reach that grade of defective action or absence of action verified in cerebellar lesions when the irritative phase has passed. Instead, some phenomena observed in the sitting and standing of our patient tally precisely with the description of asthenia and dysmetria of the animals operated on by Luciani.

Those who would pretend that clinical phenomena coincide perfectly with those observed by experimentalists betray that they do not entirely understand the problem; here we have not only the functional lesion of the cerebellum produced by the tumour, we also have (indeed, as a principal fact, as I have demonstrated) the lesions of the functions of the pons and medulla produced by compression. The excess of tone in all the muscular system is, at least in part, the effect of compression of the pyramidal tract in the pons—the equivalent of muscular hypertonicity which is usually seen below the compressed part of the spinal marrow. It might only seem strange that while the predominant compression is on the left of the pons, as is shown by the disturbance in several nerves of the cranium on that side, the lesion of the pyramidal tract is not crossed, so that it is on the left and not the right that we have a diminution of muscular force, of atrophy of the muscles of the arm, a greater augmentation of the reflexes from the tendons, and a more marked incoördination of voluntary movement. But it would be vain to expect to see the exact condition of an experiment precisely reproduced by a morbid process. On the other hand, Luciani, Russell, and Ferrier agree in attributing to each hemisphere of the cerebellum a direct or at least a predominant action on the corresponding half rather than on the opposite half of the spinal marrow; thus the predominance of certain phenomena on the left in our patient accord more with the existence of a cerebellar tumour on the left than on the right. But there is another noteworthy fact. By this time the existence of a muscular atrophy of cerebral origin is beyond a doubt; we may then admit that a muscular atrophy of cerebral origin in the left arm, and with this a diminution of force is of course associated. In face of this interpretation the objection that the phenomenon ought to be crossed has no more value, because experience has already taught us that the lesions on the right hemisphere, especially at a youthful age, are without comparison more likely to cause muscular atrophy in that part than the left hemisphere—a new instance of the mysterious difference between the two hemispheres. I believe that the atrophy of the left arm really depends on the degeneration of the right pyramidal tract and not the lesion of the left hemisphere of the cerebellum, for I know of no such fact in lesions limited to the substance of the cerebellum. I know that Marchi found fatty degeneration in the muscles of animals deprived of the cerebellum, but here we have a simple atrophy with normal electric reaction and not a degeneration. It might surprise us to see that while the motor fibres which are farther away from the pressure of the tumour manifest disturbance, the sensory ones which are nearer show none. But the surprise might be mostly theoretical, not clinical, for experience has shown in similar cases the same fact which we have observed. Indeed, a recent writer (Brissaud, if I mistake not) ascribes the fact to the motor fibres being driven against a hard body such as the underlying bone. To me this interpretation lacks probability, for the greater compression ought always to be nearest the part which presses. But other interpretations of the fact are not wanting; firstly, the structure above and below the "pons" is not identical; besides, in the mixed nerves the motor and sensory fibres do not feel equally the injury of compression. Ferra has been able to even destroy the cuneiform nucleus corresponding to the posterior cords without sensibility being at all impaired.

All, therefore, agree with the diagnosis which I have formulated, and therefore the observation I made at the beginning as to the slightness of the headache and of the inflamed eyes loses its value, as does that about the walk not being entirely characteristic of lesion of the cerebellum. The fact is that here, in addition to disorder of the cerebellum, we have an accumulation of disturbances caused by the pons and compressed medulla. I do not deny that in tumours of the cerebellum headache and inflammation of the optic nerves are particularly intense; perhaps, however, the intensity of these two symptoms is produced by the great congestion of the meninges and the brain, which depends on the impediment to the circulation of the blood in the vena magna of Galen and in the sinuses below the tentorium, but the headache has also a potent source in the irritation of the meninges by the neoplasm. We might, then, opine that the tumour was situated in the lower part of the left lobe of the cerebellum, a little away from the "dura" and the vena magna of Galen. But this would be to trust to a reasonable conjecture and not to follow the infallible method of clinical experience.

Well, experience teaches that optic neuritis may be wholly wanting—and the same is true of cephalalgia—that, in fact, tumour of the cerebellum can show no symptoms at all. Every year we get new examples of this. Not long since Ackermann noted a case in which nothing existed but gastric disturbances, especially an irrepressible vomiting; the patient was, as usual, treated by lavage. The necropsy revealed a sarcoma in a lobe of the cerebellum. For the rest, none of you are ignorant of the fact that perfectly latent tumours of the cerebellum may exist. It would, therefore, be irrational to assign too great a value to the unusual slightness of some phenomena, and not to accept a diagnosis which all the other considerations agree in demonstrating. To me, indeed, such a judgement seems so much the more confirmed that solely on this point I deemed the case worthy of your attention, and I have laid it before you hoping you may express your own observations and opinions upon it.

I will end by saying here what I have so often repeated, we do not trust of finding truths accidentally, to diagnostic labour we must apply a scientific argument. It would be useless to bring forward a hypothesis of tumour on the cerebellum, but, on the other hand, it is most valuable if one can prove that a tumour which exists on the cerebellum and nowhere else can alone account for the phenomena which we have before us. As to the nature of the neoplasm, we are only able to make a supposition; the age of the patient, the many brothers who have died, the enlarged cervical glands, and the position of the tumour all speak of tuberculosis.

That which we may safely assert is that no therapeutical treatment except surgery can possibly prevent death. Indeed, we may say more. Our patient has suffered now and again from swooning fits, but the one observed in the clinic was more serious and longer than usual, and for the first time it was associated with some convulsive movements of the upper limbs. It is enough to consider the vital importance of the centre situated in the floor of the fourth ventricle to understand how, when the above lying cerebellar hemisphere is swollen, that would be acutely compressed and rendered more than ever anæmic. It is, then, not difficult to interpret the mechanism of these losses of consciousness. But what is more important for practice is to know that they represent almost as many attempts at sudden death. We know that this is frequent in cerebellar neoplasms. Some time or other the compression and anæmia of the centre of the vagus will be increased and the functions of breathing and circulation of the blood will be immediately suspended; that day will no longer be an "attempt" at death, but sudden death itself. To judge by the increasing intensity of these swoons we may believe that this result cannot be far off.

[On the morning of Feb. 2nd the lad wished to return to Ferrara. After about ten days he re-entered the "Ricovero di Mendicità" at Bologna. Here Dr. Guido Bendani performed the operation of craniotomy, and with great skill extracted from the left half of the cerebellum a part of a tumour which the microscope showed to be fibro-sarcomatous. Its total removal was impossible. One month later the boy was still alive and better rather than worse.]

HOSPITAL SATURDAY FUND.—At a special meeting of the board of delegates of the Hospital Saturday Fund, held at the offices, 59, Farringdon-road, on Saturday evening, Mr. R. B. D. Acland presiding, it was unanimously resolved that a sum of £18,018 17*s.* be divided among the 177 participating institutions—viz., 33 general hospitals, £6661 5*s.*; 64 special hospitals, £6218 14*s.*; 37 dispensaries, £962 19*s.*; 20 convalescent homes, £1662 15*s.*; and 23 miscellaneous (including distribution and surgical appliance committees, also institutions for the gratuitous nursing of the sick poor in their own homes), £2493 4*s.* The total receipts for the past year were £21,348, as against £20,039 during the previous twelve months. The awards were more than those of 1895 by £368.

ON SOME CASES OF

UNUSUAL AND PERSISTENT "SLOWNESS" OF PULSE, PRESUMABLY DEPENDENT UPON INTERFERENCE WITH THE INTRINSIC NERVES AND GANGLIA OF THE HEART.

BY JOHN W. OGLE, M.D., F.R.C.P. LOND.,
CONSULTING PHYSICIAN TO ST. GEORGE'S HOSPITAL.

IN a comparatively recent paper on the Causes of Bradycardia,[1] Dr. Alexander Morison[2] drew attention to some of the conditions of cardiac innervation which may exist in cases of abnormal retardation of the pulse and heart's action. He regards such retardation as being syncopal in its tendency and considers that in these cases certain factors "capable of accelerating the heart's action are depressed or in abeyance." He concludes "that unknown, but not necessarily unknowable, changes in the nervous endowment of the heart are primarily causal of both transient and permanent bradycardia." He quotes Professor Dehio of Dorpat, who, in a paper on Bradycardia and the Action of Atropine upon the Sound and Diseased Human Heart, considers that the slowness of pulse "is due to nutritional changes in the automatic nerve centres in the heart, dependent in all probability upon local sclerosis of the branches of the coronary arteries leading to such centres." It is as a contribution based on such a line of thought that I venture, in this communication, to re-state and as it were rehabilitate and at greater length utilise certain cases and observations which I brought before the Pathological Society many years ago, and which I then adduced in illustration of the probable relation between peculiarities and modifications of the pulse (such as altered rhythm and rate) and interference with the automatic or intrinsic nerve elements, those distributors of impulses situated in the substance of the heart's walls. In the year 1856 I exhibited to the above-named society a specimen showing the presence of firm, yellowish-white masses of fibrinous deposit of various sizes occupying the septum of the heart's ventricles and confined to the base of the organ. On the right side of the upper part of the ventricle these masses were so prominent as to bulge into the cavity of the right ventricle, but the valves and orifices of the heart were natural. Slight atheroma of the root of the aorta existed. The patient was a man, aged thirty years, who had had rheumatic fever seven years before admission, and shortly before coming into hospital had been the subject of epileptic attacks. Before his death "fainting fits" and giddiness came on. When admitted, the heart's action was very feeble, and his pulse, though regular, was only 48 per minute, and on no occasion was it counted higher than 50. In the same year I exhibited to the society a *second* specimen showing occupation by fibrinous masses of the walls of both ventricles of the heart, and chiefly in their septum, being almost entirely restricted to the upper parts or base of the organ. Part of the fibrinous deposit was in distinct and concrete masses, but it was for the most part diffused or, as it were, infiltrated throughout the muscular structure, rendering it hard and tough. There was a tendency to the formation of an aneurysmal pouch in the ventricular septum, and hypertrophy of the left ventricle, and the aortic valve-flaps and root of the aorta were highly atheromatous. This specimen was found in the body of a woman, aged thirty-five years, who for a long time before admission into the hospital had had heart symptoms; and on admission the pulse faltered at every third beat, being then so feeble as to be almost imperceptible. In remarks on this case I quoted a *third* one—viz., that of a man under the care of Dr. Bence-Jones in St. George's Hospital,[3] and a drunkard, whose pulse on admission was only 36 in the minute. Subsequently the pulse fell to 28 per minute and was naturally the subject of much attention. Before death the pulse fell to 20 per minute. The patient was admitted for "fainting attacks" and giddiness. After death the left ventricle was found to be much dilated and its walls atrophied, and a deposit of firm, yellowish-white, fibrinous material was found on the left side of the ventricular septum, situated beneath the endocardium, which at this part was thickened and opaque.[4] In 1864 I described to the same society a *fourth* case in which the pulse was remarkably slow, and in which, after death, the endocardium covering the left side of the ventricular septum was found to be thickened and opaque; and beneath it was a thick uniform mass of fibroid deposit of a pale yellow colour and of leathery consistency. The patient, a man aged thirty-three years, was admitted into hospital with pneumonia. The pulse was, on an average, only 38 per minute, but the heart's action was regular. Later on the pulse was found to be only 28 per minute. Epileptic attacks came on before death.[5]

Searching for some possible and legitimate explanation of the concomitance of the unwonted and continuous slowness of the pulse with the structural changes in the walls of the heart I was led to the conjecture that in these cases the nerve elements which augment or accelerate the ventricular contraction, and which are, as we know, under the dominion and control of the restraining vagus nerve, were most likely the subject of a degenerative lesion, being embarrassed and interfered with by the presence of the fibrinous deposit, which was found, for the most part, at the bases of the ventricles—a locality where dissection shows that these intracardial nerve-elements are mostly congregated. Consequently, when drawing the attention of the Pathological Society to these cases, I was led to ask how far we might be justified in comparing the condition of the bases of the heart's ventricles containing the fibrinous deposits with those of the hearts of frogs and other animals of a low grade in the zoological scale which had been experimented on, and in which it had been unmistakeably shown that "a very clear and sensible connexion existed between the integrity of the great transverse fissure of the heart and the movements of the ventricles. Thus the amount of interference with the action of the heart may depend as well upon the locality which may be affected by the fibrinous deposit as upon the degree to which the deposit occupies the heart." Since the date when I made the above observations our acquaintance with the neurology of the heart, and consequently of the government and regulation of the heart's beat (that is, of the inhibitory and augmentary mechanism situated in the heart's walls[6]), especially in the case of mammals, has been much extended by physiologists. In mammals a number of small ganglia may be observed (according to recent anatomists) over a large portion of the heart's ventricles, far down towards the apex, and groups of ganglia are found in the walls of the auricles, and it is in the transverse auriculo-ventricular fissure or groove and in the basal portion of the ventricles that they are specially met with.[7] Allowing the probability of a positive and direct relation between the presence of the morbid deposits, described in my cases, in the substance of the heart's walls on the one hand, and, on the other hand, the "slowing" of the pulse, the question naturally arises as to the manner in which the effect is brought about. We know that implication of the intra-thoracic nervous plexuses by the encroachment and pressure of neighbouring intra-thoracic tumours, aneurysms, or dilated bloodvessels,[8] causing irritative lesion, as also interference with the spinal centres from which the component parts of those plexuses are supplied,[9] will, under certain conditions, materially disturb

[1] A term coined by Grob, a German physician, for "slowness" of the pulse. May we not consider any number of the pulse below 50 as being technically a "slow pulse"?

[2] THE LANCET, Nov. 23rd, 1895, p. 1281.

[3] See Hospital Post-mortem Book, November, 1855.

[4] The microscopical structure of the deposit was described by the late Mr. Gray (see Transactions of the Pathological Society, vol. vii., p. 168). It was found to be disposed "as a uniform layer beneath the endocardium and corresponded with those parts of that membrane which presented traces of chronic inflammation." It consisted histologically of "a fibrinous deposit infiltrated in the muscular tissue." It was chiefly granular, with nuclei and nucleated cells embedded in it, whilst "the muscular fibres were found much altered and presented a finely granular appearance; in other parts they were fibrillated and resembled some forms of fibrous tissue."

[5] See Hospital Post-mortem Book, 1855, No. 288.

[6] That is, to use the accepted phraseology, the catabolic and anabolic nerves. Dr. Marshall Hall invented the term *dia*-stolic. I trust that no one will venture to coin the word *dia*-bolic.

[7] It seems that the nerves and ganglia are superficially placed, for the most part, and are situated immediately beneath the pericardium.

[8] See THE LANCET, Feb. 15th, 1896, p 423, for a case in which death was attributed to pressure upon the vagus.

[9] Dr. Balfour (loc. cit. infra., p. 100) enumerates the histories of several cases gathered from medical literature, old and new, in which mechanical injury or disease of the cervical spinal cord has produced remarkable slowness of the pulse. He quotes, inter alia, the well-known

Hosted by Google

the action of the heart. May we not, considering these facts, suppose that by the presence of the morbid deposit, acting as a foreign body, the action of the intra-cardial ganglia is greatly impeded, so intimately connected as they are with the above-named intra-thoracic plexuses, and supremely controlling the energy and action of the contractile cardiac muscle? Or is it that by the pressure of the adventitious deposit the nutritional integrity of the muscular fibre is deteriorated, and thus the contractile power which should be responsive to nerve influence, abated, either (*a*) by the coronary vascular system being affected or (*b*) by the trophic nerves and their extremities being impaired[10] and, as it were, supplanted?

With respect to one or two points of "clinical history" in the above-related cases it may be noticed that of the four cases two were males and two females. Of the many instances of slow pulse studied by Dr. Morison (as also by Grob and others which he quoted) the large majority were males, as is the case in patients suffering from angina pectoris.[11] Again, as to "age," all my cases were those of individuals between thirty and forty years old. In two of them epileptic symptoms are said to have occurred. In two cases hypertrophy, and in one dilatation, of the heart was found.

The mention of the above clinical facts recalls to mind the observations of Dr. Balfour in his very useful and attractive volume, "The Senile Heart."[12] In one chapter Dr. Balfour discourses upon morbid slowness of the heart's action in old people under the name of bradycardia, stating that men are more subject to it than women, and concludes that in such cases no one special and inseparable lesion of the heart is to be found, saving dilatation, which, he observes, often associated with hypertrophy, *always* exists. He states that the myocardium in such cases is *not* specially feeble or fatty. Again, Dr. Balfour describes with much exactness the frequent association of epileptiform attacks with senile bradycardia, and refers at great length to those cases in which pseudo-apoplectic and epileptic symptoms existed associated with slowness of pulse, described by Stokes and Adams long ago, in which it appeared to them that the cerebral symptoms were contingent upon the condition of the heart, the result, in fact, of cerebral anæmia.

Of my four cases (as above noted) epilepsy occurred in two, but their ages placed them in a different category to those described as senile. Respecting the coincidence of epileptic or epileptiform convulsions in cases of preternatural retardation of the pulse, I would here refer to two remarkable instances of the same, comparatively recently recorded, to which my attention has only just been called. I allude in the first place to the case related by Dr. St. George Mivart in THE LANCET of Jan. 3rd, 1885, and that by Dr. Gibbings in THE LANCET of Feb. 14th following. Mr. Mivart's case, a man aged sixty-one years, was one of epileptiform attacks of a syncopal character, the pulse being counted as low as 26, 24, and 20 per minute, the heart's beat synchronising with the radial pulse.[13] No after-death examination took place, but it was surmised that there were aortic stenosis and fatty heart. Dr. Gibbings' case, that of a man aged sixty-six years, was also one of epileptiform and syncopal convulsions. The pulse varied from 44 to as low as 12 per minute, being synchronous with the heart's beat, and the temperature at one time was only 96° F. and never reached 98°. The convulsive attacks were so frequent that on one occasion, with the exception of one hour, they continued during the whole night. The patient died suddenly. On post-mortem examination no morbid appearances in the heart or bloodvessels were found.

Regarding the interesting case (one originally of acute syphilitic laryngitis) recorded by Mr. Pugin Thornton,[14] and quoted by Dr. Morison, the heart (as noticed by Dr. Ransom) would cease to beat on several occasions, and on one occasion, during a moderate convulsive attack, it failed to beat for fifteen seconds. His opinion was that the peculiarity of pulse was dependent on an affection of the pneumogastric nerve caused by syphilitic poison. Assuming that the retardation of the pulse has something to do in these cases with the epileptiform or syncopal seizures, there surely must be some additional coöperating influence—some other factors availing in the problem. Most likely some morbid condition of the minute vessels or intimate structure of the brain must be considered to have co-existed; otherwise the seizures would surely be more frequently noticed, and would be more persistent, considering the permanency of the slowness of the pulse.

In the interesting work by the late Dr. P. M. Latham on subjects connected with Clinical Medicine, when referring to the secondary diseases of the brain[15] (quoting from Dr. Burrow's writings on Disorders of the Cerebral Circulation) Dr. Latham refers to the "strange disguise" of cerebral symptoms, such as delirium and convulsions, having their origin in the heart. He observes: "Here surely there is more than we can account for from the known pathology of blood and bloodvessels and from derangements of the circulation." Dr. Latham makes no mention of cases of slow pulse, but says much about the baneful action upon the brain of the vehemence of the heart's action. Dr. Morison quotes the case of Napoleon I. as an epileptic, whose pulse is stated by Dr. Comby, on the authority of his physician, Corvisart, to have been, habitually, only 40 per minute. Dr. Morison, quoting from Dr. Comby, considers it probable that Napoleon's attacks were syncopal.[16]

In the previous remarks the connexion between the abnormally slow pulse and the epileptic seizures has been looked upon as one of cause and effect.

It would appear, however, that a class of such cases exists in which the peculiarity of pulse and the epileptic tendency may be the results or outcome of a general condition common to both—viz., to uræmia. In connexion with this subject I will draw attention to a communication which I have only recently met with in the

case under Mr. Holberton's care (see Transactions of the Royal Medica and Chirurgical Society, 1841, p. 78), alluded to by Dr. Morison, in which inhibitory effects on the heart brought down its pulsations to *seven and a half beats per minute*, and this condition lasted for many years. He also enumerates several instances in which people in perfect health had persistently low pulse. Dr. Morison aptly quotes the remarkable case of Professor Czermak, who is said to have been able to retard or arrest the action of his own heart by producing pressure on the vagus by means of an osseous tumour in the neck. In the volume by Dr. Balfour, to which I shall allude later, p. 103, the case of the Indian Fakirs is quoted, who are said (on the authority of Dr. Braid) to be able to slow the heart's action and diminish the force of its beats by compression of the "accessory" nerve in the neck.

[10] Here it may be well to call to mind that, as research has shown, in some animals other influences on the regulation of the heart's movements, in addition to those from direct nerve influence, exist. We know that the muscular elements of the heart possess, in certain lower animals, an inherent physiological property of rhythmical action, apart from idio-motor nerve or ganglion influence: and that small fragments of those portions of the ventricular muscle of the frog and tortoise which are devoid of nerve cells will, under certain conditions, perform, for a long period, spontaneous rhythmical movements, in all respects the same as the natural and regular beat of the uninjured ventricle.

[11] I have not entered into the consideration of the pathology of the deposits in the heart's walls, as to whether, for example, they were the results of ordinary inflammatory action, or, what is more probable, whether they were of a more specific, and possibly of a syphilitic, nature.

[12] A volume especially interesting as an example of applied physiology, showing full knowledge of the literature of its subject, and rendered the more instructive by lucid and well-made diagrams.

[13] Of course, cases in which the slowness of the pulse is merely the result of the heart's contraction not reaching in its effects the periphery (the blood wave or shock not being propelled as far as the radial artery) are obviously not to be classed as cases of "slow" pulse, in reality. The importance of this caution was long ago insisted upon by Dr. Heberden—viz., in his "Remarks on the Pulse," read at the Royal College of Physicians of London in 1768. Alluding to a patient whose pulse was not above 12 or 16 in the minute he says that in all instances where the pulse is below 40 "I suspect that the artery beats oftener than it can be felt, because such pulses are usually unequal in their strength, and some of the beats are so faint as but just to be perceived, so that others probably still fainter are too weak to make a sensible impression on the finger."

[14] Transactions of the Clinical Society, vol. viii., p 95.

[15] See Lecture XXV.

[16] Napoleon's disease, to which he had for many years been liable, is on several occasions alluded to by Viscount Wolseley in his recent work, "Decline and Fall of Napoleon," and is therein described as being a "mysterious malady," the exact nature of which was not permitted to be known. "When under its influence," remarks Lord Wolseley, "he was incapable of all useful mental and bodily exertion, had great difficulty in keeping awake, and his drawn features and expression bespoke both physical pain and mental depression." During the battle of Waterloo he was for several hours motionless at the table and often asleep, and when flying from the field became so drowsy that he was hardly prevented from falling from his horse. This condition generally followed a period of great mental and physical prostration, sometimes accompanied by great exposure to weather. Lord Wolseley states that Napoleon's disasters in Russia and at Dresden and his final overthrow at Waterloo were accounted for by this mysteriously occurring malady. If Napoleon had epilepsy, as Corvisart is said to have stated, is it not possible that the peculiar mental condition to which Lord Wolseley affirms that he was so disastrously liable, was the immediate result of the epileptic attacks to which he was at times thought a prey? We know how often such attacks, especially those of the "petit mal," leave a hebetude and often even aberration of mind, such as is attributed to Napoleon, and even more serious results. Mahomet is said to have suffered in the same manner and from the same cause—namely, severe indigestion of food. (See Walter Scott's Life of Wellington, vol. vii., p. 344). Was it not also the same with our great Duke of Wellington, where death might probably have been prevented by a timely emetic (see THE LANCET, vol. ii., 1852, pp. 355-6)?

Hosted by Google

French journal, *La Semaine Médicale* for 1892, p. 265, by Dr. Comby, entitled "Le Pouls lent permanent." From his own experience, the author describes, and also quotes from others, certain cases of permanently slow pulse in which serious symptoms, such as attacks of dyspnœa, giddiness, epileptic and apoplectic attacks occurred. In all these cases the renal secretion was found to be materially diminished and to contain albumin, and the conclusion arrived at was that the above-named symptoms were uræmic in character, inasmuch as both the slowness of pulse and the grave symptoms disappeared when the patients were restricted to an entirely milk diet by which the amount of urine was increased and the albumin contained therein was reduced in amount. I would also, in conclusion, draw attention to Dr. Regnard's Thèse pour le Doctorat en Médecine presented in July, 1890, entitled, "Etude sur la Pathologie du Pouls lent permanent," based upon a copious French and English literature on the subject. His conclusions are as follows. Every durable lesion causing irritation of any portion of the moderating apparatus of the heart may suffice to cause a permanent slowness of pulse and give rise to the aggregate of symptoms studied. He observes that the nervous irritation may have many causes, as local anæmia (influence of atheroma on the peripheric circulation and blood-supply to nervous centres), deficient blood-supply of the bulbous parts of the pneumogastric, tumours of the coverings of the bulb, or of the mediastinum acting on the vagus, morbid excitation of the laryngeal and gastric branches of this nerve; but most frequently it is some affection of the heart itself, as fatty degeneration, or endocarditis, or coronary atheroma. The predisposing conditions are stated to be artéro-sclerosis (syphilitic, alcoholic, gouty, rheumatic). As to treatment, the indications are to restore the heart's failing energy, to lower arterial tension, which, at the outset, diminishes this energy, to strive against cerebral ischæmia by such remedies as the iodides, nitrite of amyl, trinitrine, caffeine, nux vomica, sparteine, and strychnia. But vaso-constrictors such as digitaline, ergotine, and quinine, are to be avoided.

POSTCRIPT.

With regard to the allegation that Napoleon I. was, as Julius Cæsar and Mahomet were said to have been, an epileptic, and also that his pulse was never known by his medical attendants to have counted more than 40 per minute, I have been at the pains to try to obtain authentic statements on these points. These statements have been copied from one medical work into another, both English and French, rather freely, and are said to be so quoted on the authority of the Emperor's private physician, Corvisart; and quite lately, in Dr. Osler's "Principles and Practice of Medicine," the statement is repeated (page 688). Much has been written in recent times, as well in England and America as in France, about the Emperor's private life, but I have failed to find in any personal memorials, whether in those (assumed to be veracious) of Constant, who as his valet shaved and daily attended to him for fifteen years—viz., from his departure from the Marengo to his taking leave of Fontainebleau before going to Elba—or in those of his secretary, clear proof that he was the subject of epilepsy. The Emperor appears to have been habitually careful as to his food, eating sparingly, though very often too quickly (chiefly mutton and chicken, with Chambertin wine), and able to recruit his strength by falling asleep almost at will, and this often during battles, as at Wagram and Bautzen. After long watching and anxiety (having possibly eaten heartily) he was apt to be affected by "heaviness" and indigestion. Thus after the battle of Dresden he returned to Dresden in pelting rain on horseback; and on the next morning, after three or four days of extreme fatigue of body and mind, having had but scanty food or rest, he is stated to have suffered from eating largely of mutton stuffed with garlic; and at the battles of Borodino and Leipzig his efforts are said to have been paralysed by his attacks of indigestion. Of the various maladies from which in the last years of his life—i.e., whilst at St. Helena—he suffered, a good account is given in the interesting Diary of Dr. O'Meara, who attended him. He is described as being very liable to "colds" owing to his unwillingness to take open-air exercise, to swellings in the face from teeth trouble, to various forms of indigestion, and, finally, to œdema of the legs and to symptoms of enlarged liver (October, 1817), but I find no reference to anything of the nature of epileptic or kindred affections. Dr. O'Meara, however, throws some light on the question of Napoleon's pulse during his attendance. The Emperor had said that very often he could not feel his own pulse or any beating of the heart, and this was thought by O'Meara to depend on obesity.[17] He remarks: "I had observed that the Emperor's circulation was very feeble, rarely exceeding 58 or 60 in a minute, and most frequently was 54." This statement suffices to verify the general opinion as to Napoleon's slowness of pulse, although Corvisart, as above-said, is thought to be the authority. On this point Dr. Huchard,[18] Médecin de l'Hôpital Bichat, informs my friend Dr. Keller of Paris that Corvisart had not *written* anything about the Emperor's pulse, but that his friends had been told of its slowness by him. In a letter to me from a well-known physician in Paris the writer amusingly presumes that the idea of Napoleon's having been the subject of epilepsy is most likely a "*British* invention" (*fabrication Anglaise peut-être*), but admits that his heart's pulsations were below normal in number.

In Dr. Huchard's work, above alluded to, several lectures are devoted to the subject of "Artério-sclérose," and much attention is given to the multiplicity of the localisation of the anatomico-pathological process in various organs, especially of the kidney, liver, lungs, brain, &c. The affection causing the bradycardia, which, along with syncopal and pseudo-epileptic and apoplectic attacks, exists in cases named after Stokes-Adams, he has designated "*cardio-bulbaire*," the lesions not being confined exclusively, as some thought, to the heart, the anatomical cause lying in the cervical spinal cord, or the bulb and the vagus nerve. When there is co-existing affection of the vessels of the kidney we have uræmic convulsions, &c. Dr. Huchard[19] classifies the various forms of bradycardia which may exist, as follows—viz.: (1) physiological; (2) those accompanying convalescence from various diseases; (3) toxic; (4) reflex; (5) nervous; and (6) cardiac in origin.

NOTES ON STONE IN THE BLADDER.

BY D. F. KEEGAN, F.R.C.S. ENG.,
BRIGADE-SURGEON-LIEUTENANT-COLONEL, INDIAN MEDICAL SERVICE (RETIRED).

III.[1]—COMPARATIVE SAFETY OF LITHOLAPAXY, LATERAL LITHOTOMY, AND SUPRA-PUBIC LITHOTOMY IN PATIENTS AT ALL AGES.

TABLE III.—*Showing the number and result of Litholapaxies Lateral Lithotomies, and Supra-pubic Lithotomies performed on patients at all ages in the Punjab, North-West Provinces, and Oudh, and in the Bombay Presidency during five years ending Dec. 31st, 1895.*

Nature of operation.	Number of operations.	Cured.	Died.	Percentage of mortality.
Litholapaxy	10,073	9,665	399	3·96
Lateral Lithotomy	7,201	6,407	794	11·02
Supra-pubic Lithotomy ...	147	86	61	42·17

THIS table has been compiled from data supplied by the Official Medical Reports published in India, and I have again counted the results of all operations tabulated in the "discharged otherwise" column as deaths. It is somewhat unfortunate that in the official returns of operations for stone performed throughout India the ages of patients are not classified in quinquennial and decennial periods, for if this were done the value of such returns would be much enhanced. The age of the patient and the weight of the calculus are two such very important factors in determining the results of litholapaxy, lateral lithotomy, and supra-pubic lithotomy, that when we are not in possession of such

Hosted by Google

factors it is almost impossible to gauge the relative mortality of these three operations. In lateral lithotomy, especially, the age of the patient and the weight of stone removed are most important factors in the solution of this problem. It would, therefore, be well if the ages of patients under fifteen years who undergo operations for stone in the bladder were classified in triennial or, at least, in quinquennial periods, and if the ages of patients between fifteen years and very advanced life were arranged in decennial periods. This is a matter which might profitably engage the attention of administrative medical officers in those provinces of India wherein stone in the bladder is prevalent. The table appended, although unfortunately it does not show the average ages of patients or the average weight of stone removed, is, in some respects, a valuable one and tells its own tale. A glance at it shows that litholapaxy is being practised largely throughout India and that it is gradually superseding the time-honoured lateral lithotomy. A further examination of this table shows that the percentage of mortality following litholapaxy was only 3·96 as compared with 11·02 following lateral lithotomy. In the absence of all reliable information regarding the relative ages of patients submitted to operation, and the weights of calculi removed by these two surgical procedures, it would not be fair to institute comparisons regarding the mortality which followed them. But I think that there can be little doubt that the average weight of calculi removed by lateral lithotomy was greater than that extracted by litholapaxy, and that at the same time there was no great difference in the ages of the patients treated by these two methods. It is certainly a subject of congratulation that the percentage of mortality which followed litholapaxy was but 3·96 in a total of 10,073 patients submitted to this operation—a mortality which incontestibly proves that there are at the present day a large number of skilled litholapaxists in India. Continuing our examination of the table we find that in a grand total of 17,421 operations for stone in the bladder supra-pubic lithotomy was performed only 147 times, and that the rate of mortality which followed it was 42·17 per cent. This rate of mortality is no doubt high, but not so high as it is in England and throughout Europe, when supra-pubic lithotomy is performed for very large calculi. It is true that the official reports published in India give no information regarding the average weights of calculi removed or the average ages of patients submitted to supra-pubic lithotomy; but knowing how unpopular this operation is among surgeons in India, I feel pretty certain that the average weights of the calculi in these 147 operations must have been very considerable. Judging from the information contained in Table II.[2] it is but only reasonable to infer that the great majority of these 147 operations were performed on adult males, because Table II. showed that in the Punjab during the year 1895 there were but two supra-pubic lithotomies performed on boys, and we may reasonably take the practice in the Punjab in 1895 as an indication of the methods which prevailed in other parts of India during the five years under review.

In recent years the trend of surgical opinion in India has been in the direction of restricting supra-pubic lithotomy to very narrow limits. Expert litholapaxists in India nowadays attack a stone weighing between two and four ounces with the utmost confidence, and are therefore seldom obliged to fall back upon supra-pubic lithotomy, and when they do meet with a stone which defies the power of a No. 16 or a No. 18 lithotrite they are more inclined to perform a lateral lithotomy or a perineal lithotrity than a supra-pubic lithotomy. I feel certain that in India perineal lithotrity will within the next decade occupy the place now held by lateral lithotomy in dealing with very large or hard calculi in adult males which resist the power of the largest lithotrites which can be safely introduced into the bladder per urethram. And should this opinion prove true the death-rate of a very important class of cases will be greatly diminished. In the North-West Provinces and Oudh there were twenty perineal lithotrities performed during the year 1895 without a death; but as no information is forthcoming regarding the average weight of calculi removed or of the ages of patients treated, I can only conjecture that these operations were undertaken for the removal of very large calculi from the adult male bladder. Some six months ago I had an opportunity of examining a very powerful lithotrite constructed by Messrs. Weiss and Sons for a surgeon living in a district of the Punjab where very large calculi are frequently met with. This lithotrite was of the fully fenestrated pattern; the stem corresponded to No. 20 (English scale), and at the angle it measured No. 26 (English scale); the length of the blades was 7½ in., or shorter than an ordinary No. 16 lithotrite by about 3 in. It was constructed with a view of crushing large calculi which could not be dealt with by litholapaxy, and I am informed that it answers its purpose admirably. No doubt we shall hear more details regarding the capacity of this giant lithotrite from the surgeon who is so fortunate as to have many opportunities of using it, and full particulars regarding the cases in which it has been used. Such a lithotrite introduced through a small incision in the prostate would readily break up a mulberry calculus weighing between four and six ounces—indeed, few calculi could resist its crushing power. The success achieved by Mr. Reginald Harrison, and more recently by Mr. Herbert Milton, in perineal lithotrity will, no doubt, stimulate surgeons in India to adopt this method in preference to lateral lithotomy. We know how the death-rate following lateral lithotomy increases in direct ratio with the size of the stone to be removed, and that this is especially true when we have to deal with patients at the middle period of life. This mortality is in a great measure due to the large incision made in the prostate, which sometimes unfortunately encroaches on the capsule of the gland, and to the almost inevitable bruising of the neck of the bladder and of the tissues of the perineum in the extraction of a large, unbroken calculus by this route. It was with the intention of counteracting these risks that supra-pubic lithotomy was revived; but experience has taught us that supra-pubic lithotomy is not more successful than lateral lithotomy is in dealing with very large calculi, and, therefore, I think that perineal lithotrity should get a fair and extended trial in these very difficult cases.

As years go by supra-pubic lithotomy will be less and less employed in India, and will be reserved for those comparatively rare cases to which it is so eminently adapted. The heavy mortality which followed 147 supra-pubic lithotomies may come as a surprise to those who have long laboured under the impression that the natives of India bear all operations for stone in the bladder with a truly wonderful immunity from fatal results. The general surgeon in Europe, who through lack of opportunities can hardly be expected to be very proficient in the use of the lithotrite, marvels at the great success which the skilled litholapaxist in India achieves in dealing with large stones in young and old patients; and, naturally enough, he is inclined to ascribe the great success of his Indian *confrère* in the treatment of stone in the bladder to the greater tolerance of operative interference on the part of the native of India as compared with the native of Europe. He is disposed to account for this remarkable tolerance by ascribing it to the placid disposition of the native of India, to the non-stimulating character of his vegetable diet, and to the fact that he seldom, if ever, indulges in alcoholic beverages. And recently, I note, that the marvellous residual kidney power of the native of India has been pressed into the service to account for the excellent results achieved by litholapaxists in India. Mr. Herbert Milton of Cairo, whose recent papers on lithotrity[3] have so deservedly attracted much attention, has referred to the extraordinary tolerance of Orientals to all operations and diseases connected with the urinary apparatus.[4] And no doubt such tolerance does exist among Ethiopians and their descendants, who form no inconsiderable proportion of the native patients who throng the hospitals at Cairo and Alexandria. But the Egyptian Fellahin, Soudanese, Nubians, and Copts are in temperament very different from the Aryan races of India, and I need scarcely point out the great divergence in physical and intellectual characters between the lower classes of the population of Egypt and those who inhabit our great dependency. An acute, intelligent, and keen-witted Hindu is very different in build and temperament from a sluggish inhabitant of the Egyptian Delta; and the male generative organs of the Soudanese, for example, are altogether on a much larger scale than those of the majority of the population of India. Mr. Herbert Milton tells us that he has been frequently able to introduce a No. 22 evacuating cannula (English scale) into the bladders of his patients at Cairo, and that he usually works with a

No. 18 or a No. 20 evacuating cannula. Most surgeons who have done much stone work in India will, I think, bear me out when I state that it is but comparatively seldom that a No. 20 evacuating cannula can be readily passed into the bladder of a Hindu. Then how can we account for the great measure of success achieved by the skilled litholapaxist in India, if it be not due to the greater tolerance of operative interference by the native of India as compared to that of the native of Europe? The explanation is very simple. The main reason why litholapaxy is more successful in India than in Europe is that, as a general rule, it is done more thoroughly and more skilfully in the former than in the latter. And the reason why it is done more skilfully in India than in Europe is explained by the frequently repeated opportunities which surgeons in India enjoy of practising this operation. But we surgeons who have passed many years of our lives in the calculous districts of India, must not plume ourselves because we happen to be very expert at working with the lithotrite, and we need not be very proud because we are able to crush a stone in the bladder skilfully and with little danger to our patients. For we have done no more than take advantage of the unrivalled opportunities afforded us in this special department of operative surgery.

Now, if the great success obtained by surgeons in India in litholapaxy depended solely on the peculiarly favourable conditions of their patients, then the novice in litholapaxy in India should obtain as good results as a master of the craft. But this is notoriously not the case. I may cite three examples out of many to illustrate this point. In the July number of the *Indian Medical Gazette* for 1892 I gave an analysis of the first 500 litholapaxies performed at the Indore Hospital, Central India, on patients at all ages. Deducting the litholapaxies in boys there were 286 operations in males between fifteen and ninety years of age, with 11 deaths, or with a death-rate of 3·84 per cent. But when I come to examine this mortality more closely I find that 7 out of the 11 deaths occurred among our first 52 litholapaxies, leaving a balance of 234 litholapaxies with only 4 deaths. The death-rate among the first 52 litholapaxies was 13·4 per cent., while it was only 1·7 per cent. among the last 234. There was no marked difference in the ages, caste, and general health conditions of the patients who constituted the first division of 52 and the second division of 234, and the average weight and composition of calculi removed from both sections of patients did not differ materially. A death-rate of 13 4 per cent. in 52 litholapaxies was certainly not a very brilliant result; but a death-rate of 1·7 per cent. in 234 litholapaxies left little to be desired. The second instance refers to the work done at Hyderabad, Sindh. Brigade-Surgeon-Lieutenant-Colonel Forbes Keith has placed at my disposal a tabular statement of all operations performed by him for stone in the bladder at Hyderabad during five and a half years ending May, 1894. The number of operations was 1933. Eliminating all the lateral lithotomies in boys and men and 57 litholapaxies in females, I find that he performed 676 litholapaxies in adult males with 22 deaths, a rate of mortality of 3·2 per cent.—a result highly satisfactory. He, however, lost 16 patients in his first 111 cases, a death-rate of 14·4 per cent. In his last 565 operations he lost but 6 patients, a death-rate of only 1·06 per cent. As in the case at Indore, there was no marked difference in the ages, caste, and general health conditions of the patients, or in the average weight and composition of the calculi removed in his first 111 and his last 565 litholapaxies. The third instance refers to Surgeon-Lieutenant-Colonel Freyer's experience. In reply to my questions on this subject he writes: "I find that amongst my first 50 litholapaxies there were 3 deaths, or 6 per cent.; but it must be remembered that my earlier cases were selected, the worst cases being subjected to lithotomy. My results have gradually improved as I have gained experience of the operation, so that amongst my last 300 litholapaxies there were only 3 deaths, or 1 per cent., though I rarely use the knife now. As I gain experience of Bigelow's operation amongst Europeans I am gradually coming to the conclusion that the European stands the operation better than the native of India." Then how can we account for the vast difference in the mortality which followed our first and last series of litholapaxies? The answer is easy. We were learning our work at the beginning, and as soon as we had gained experience and confidence in performing the operation, and had learned how to use the lithotrite with skill and precision our success increased most rapidly. And so, after all, it comes to this, that the bladder and urinary organs of the natives of India, like those of the natives of Europe, become tolerant of the use of the lithotrite when the surgeon has learned the art of manipulating it with skill and precision.

It is, perhaps, a somewhat ungrateful task to dispel a fondly cherished and consoling illusion of the unskilled litholapaxist in Europe, when he ascribes the great success achieved by his Indian *confrère* in crushing vesical calculi to conditions in the latter's patients which have only a mythical existence. The truth, however, must be told, disagreeable as it often is to hear it; and now, I trust, we shall read and hear no more about the tolerance of the Indian bladder, and of those mythical Indian patients who, though suffering during a long series of years from stone in the bladder, are lucky enough to retain their kidney power unimpaired. In few operations in the whole range of surgery are constant practice and the personal factor of the operator of greater importance than in litholapaxy. No surgeon need hope to acquire a practical familiarity with the lithotrite until he has performed between fifty and a hundred litholapaxies, and even then, he has still much to learn. In the beginning he may be so fortunate as to get a run of a dozen simple and straightforward cases which may not tax his powers of manipulation too severely, but the difficult cases are sure to turn up sooner or later. Then how, it will be asked, is the general surgeon in Europe, who only meets with cases of stone in the bladder at fitful intervals in his professional career, ever to acquire a practical familiarity with the lithotrite? Again the answer to this question is simple. The general surgeon in England, and throughout Europe, as a matter of fact, seldom, if ever, acquires this familiarity, and he passes away or retires from practice without ever having acquired it. The span of active professional life is too short to learn the art of performing litholapaxy with dexterity and safety to one's patients unless a surgeon has been so favourably placed as to be afforded frequently repeated opportunities of working with the lithotrite. The fact of the matter is that in England and throughout Europe, there are not enough cases of stone in the bladder to go round among the general surgeons, and so if any young surgeon cherishes the ambition of developing into a skilled litholapaxist before middle-age shall overtake him he should go to Egypt or India to learn this special operation. With this object in view, a year spent in the hospital at Hyderabad, Sindh, would be worth a lifetime of practice in England.

Cresswell-gardens.

A CASE OF MUMPS, WITH CEREBRAL SYMPTOMS AND HIGH TEMPERATURE;

WITH A REVIEW OF SOME OTHER CASES PREVIOUSLY RECORDED.

BY F. LUCAS BENHAM, M.D., M.R.C.P. LOND.

THE following are the notes of a case of some interest which I lately attended in conjunction with Mr. H. G. Brigham.

The patient was a lad, barely sixteen years of age, who was at school a little way out of London, where there had recently been a few cases of mumps. On Nov. 1st, 1896, an attack of mumps set in, with ordinary symptoms. The left parotid gland swelled first, then the other became swollen before the first had subsided. He was kept in bed. On the 2nd the parotid glands were still swollen. He was kept in bed part of the day. Some pain was felt in the left testis. On the 3rd he seemed much better and was allowed to go home to London, but had to walk more than a mile to the station. On the 4th he was not so well. The testis was distinctly swollen. He was feverish, but had no rigor or vomiting. The temperature was 104·7° F. in the evening. On the 5th he was still kept in bed and was very feverish. The temperature was 103°. There was no swelling over the parotid glands. The left testis was somewhat swollen and tender and the scrotum was red. There was a fine papular rash, something like that of scarlet fever, on the outer aspect of the left forearm. The buttocks were slightly erythematous,

Hosted by Google

but there was no distinct rash elsewhere. The tongue was moist and coated with a thick yellowish fur. There was no swelling or redness of the tonsils or throat. There was some headache, but the patient was cheerful and wished to get up. The pulse was not very frequent. He was still kept in bed. He was ordered three grains of calomel and a diaphoretic mixture. The temperature was 104·8° in the evening. On the 6th the temperature was 105° and the pulse 120. The tongue was moist and thickly coated; the velum palati looked raw and dry and was partially covered with tenacious mucus, but the throat was not red or sore, and the tonsils were not swollen. The rash had quite disappeared. Tache cérébrale was visible on the abdomen. He was thirsty. He had been sick on the previous day after taking the powder. The bowels had been opened two or three times. The eyes were natural and the pupils normal. He had been delirious, wandering, and talkative, asking for beer, &c., at night. The following mixture was ordered three times a day; half a grain of potassio-tartrate of antimony, fifteen grains of carbonate of magnesia, half a drachm of sulphate of magnesia, and peppermint water to one ounce. He was also to be sponged, when hot, with vinegar and water; and he was to have a milk diet. At 9.30 P.M. he had been dull, drowsy, and heavy, almost in a state of stupor, from which he could be momentarily roused without much trouble, all day. The temperature was 103·4° and the pulse 108 and regular. He had vomited two or three times curds and bile. The bowels were opened twice. The testis was more swollen; the scrotum was red and œdematous. There was frontal headache, but not very intense; the patient lay on his side and slept, but sleep was not continuous and was broken by horrible dreams of accidents, &c. The tongue was moist and cleaner; there was no pain in the back or limbs, but he disliked being disturbed. He had perspired freely. On the 7th he had had a restless night, but was brighter and more cheerful in the morning. His head was clearer, the headache was gone, though it was still brought on by movement. The temperature was 102·6° and the pulse 100, dicrotous. The tongue was moist with yellowish fur. There was no more vomiting. The bowels were opened three times. He took milk badly, and was ordered beef-tea, toast, cooked apples, &c., and to continue the medicine, The left testis was more swollen, and tender on pressure. He passed urine involuntarily, as he had done the day before. The temperature was 103·8° in the evening, and the pulse 100. On the 8th he had slept better, though he was restless; he had taken more liquid food. There was no vomiting. The bowels had been opened eight times. In the morning he was much better in all ways. His temperature was 99·2° and the pulse 80 and regular. The headache was almost gone. His mind was clear and he was more lively and natural. The tongue was still coated but was clean at the tip. There was copious epistaxis in the morning. He complained of pain over the lower part of the sternum; on auscultation the sounds of the heart were found to be quite normal. The testis was still very large and tender and the scrotum œdematous. The temperature was 101° in the evening. On the 9th he had slept better, but was still restless. The temperature was 100·2° and the pulse 96. The tongue was slowly cleaning from the tip. The epistaxis was renewed in the morning. The headache was gone. The left testis was smaller, but painful and tender, and there was much œdema of the scrotum. The right testis was somewhat tender also, but was not swollen. The temperature was 102·2° in the evening. The medicine was discontinued. On the 10th the temperature was 97·8°. The tongue was cleaner. The left testis was smaller and the right testis tender; hot fomentations were applied. At 9 P.M. the patient looked well. The temperature was 97·6° and the pulse 72. The tongue was clean. The appetite was becoming ravenous. On the 11th he was still in bed, but convalescent. On the 13th he sat up for the first time. He slept while sitting in a chair; both arms and legs twitched during sleep. The bladder had been irritable during the illness, but this was now all right. On the 15th he left the room for the first time, but was very shaky; he was weak on the legs and had to be assisted on returning upstairs.

The testis subsequently underwent considerable atrophy, as is usual, I believe, in such cases as this.

Remarks.—The nervous phenomena which may complicate mumps are not novelties; they have been observed and remarked upon from time to time for a long while. But all the same they are infrequent, even very exceptional, considering what a common disease mumps is. They are said to be more common in some epidemics than others. The subject is mentioned in standard text-books of medicine, but generally in a vague and inaccurate way. It is, perhaps, because mumps is generally such a trivial complaint that so little attention is devoted to its curious occasional phenomena. But surely it is an error to style the disease, as is done in more than one text-book, "Idiopathic Parotitis," which is quite a different thing. I should like also to raise the question whether meningitis is a possible complication as it is sometimes stated to be. Some writers, by-the-way, think proper to place mumps among diseases of the mouth, &c., instead of with general and infectious diseases. A good many cases complicated with brain symptoms have now been put on record, but they are only to be found here and there in various periodicals, British and foreign; it seems, moreover, that the literature of the subject is more abundant in other countries, especially France and America, than in this. These cases are remarkable, both on account of the striking nature and sudden appearance of the symptoms, and on account of the obscurity of their pathology, which is still a mystery. Fortunately, even although the symptoms be alarming, death very rarely takes place. Moreover, when death does occur in mumps, it seems often to be due to some indirect complication which may almost be called accidental. I will refer briefly to the fatal cases that I have been able to discover, either described or mentioned. Three fatal cases are cited by Haldeman.[1] The first of these, complicated with orchitis, died from acute pneumonia, which set in on the fifth, and was fatal on the eleventh, day of the illness. The author ascribes the pneumonia to embolism. The second case, in which both parotids and both testes were involved, succumbed to the bursting of an abscess of the liver into the lungs and air-passages, causing asphyxia on the thirteenth day. His third case is that of a woman, seven months pregnant, who aborted on the fifth day and died from septicæmia two days later.

A remarkable case of sudden death in mumps is related by Gillet.[2] The patient was a young conscript, in whom swelling of the right parotid gland set in, which spread to the submaxillary gland also; he did not take to bed or rest at once. On the fourth night he suddenly awoke, rose up and tried to walk, but fell in a state of complete syncope; he rallied a little, but soon became collapsed again and died. It is stated that he could breathe and swallow during the attack. Only the parotid gland was examined post mortem. Death was ascribed to embolism of one of the arteries at the base of the brain due to cardiac thrombosis consequent on endocarditis. In a case reported by Hamilton[3] and in another by Shreve[4] furious delirium came on suddenly, with great excitement, and attended in the former with opisthotonos and muscular rigidity, and death ensued in each in two or three days. Other fatal cases have been recorded, two by Lindsley,[5] another by Pollard,[6] a few others (mentioned by Lannois and Lemoine) by various French observers, but no details are furnished when quoted, and I have not obtained access to the sources of information. Niemeyer[7] says: "Cases have also been recorded where, in the course of idiopathic parotitis, fatal meningitis has been developed." Eberle[8] also speaks of a fatal case with convulsions. I am not aware, however, that a post-mortem examination was made in any of the fatal cases referred to or that there was positive evidence of meningitis in any of them. From a survey of all the cases to which I could find a reference and have been able to peruse the details it seems that the cases of mumps with cerebral complications fall into three different classes according as the nervous symptoms are marked by: (*a*) high fever and delirium; (*b*) insanity; and (*c*) paralysis.

A.—The case above related is a characteristic example of the first group. Cases of this sort are met with, I believe, only in males, never in children, and chiefly in lads about the age of puberty or in young men, and is almost always, if not invariably, associated with orchitis, though of course orchitis often complicates mumps without there being any serious constitutional disturbance. Lynch[9] states that high fever and delirium may occur in mumps when the disease is

confined to the parotid glands, but I have not been able to find the account of any such case where the presence of orchitis is not mentioned. It may be that the brain and testes are affected in common simply because of the intensity of the disease, but the constant association of the brain symptoms with severe orchitis suggests the possibility of some causal relation between the two. In some cases—e.g., those related by Trousseau,[10] Hall,[11] Walmsley,[12] Davis,[13] and Lees,[14] the extreme febrile symptoms and delirium supervened on the subsidence of the swelling of the parotids and disappeared on the manifestation of orchitis. It is to this particular feature that Trousseau calls attention, and many readers will most likely recollect his vivid account of the two cases which came under his own notice with an interval of twenty years. But in other cases (and they form the majority, as far as my inquiries go), as in the case related in this paper, also those by Hamilton,[15] Appleyard,[16] Beale,[17] Monro,[18] Parrott,[19] Doudney,[20] Minot,[21] Shreve,[22] Sorel,[23] Janson-Zuède,[24] and Lynch,[25] orchitis appeared first, and was attended either immediately or after a short interval, by high temperature (sometimes reaching 106° or 107° F.) and severe febrile symptoms, such as delirium and other nervous phenomena, and the local inflammation and general symptoms subsided *pari passu*. The nature and pathology of these cases is uncertain and obscure. By some observers and writers the nervous symptoms have been assigned, rather hastily I think, to meningitis; but in almost all the cases referred to above, this cause is, to say the least, very doubtful. The symptoms are hardly those of meningitis, and the cases certainly bear very little resemblance to the description, say, of epidemic cerebro-spinal meningitis. Moreover the difference in mortality is very great. Even in Hamilton's and Shreve's cases *(vide supra)* the symptoms do not point conclusively to meningitis; the inference is rather that death took place from exhaustion consequent on violent excitement, but no necropsy seems to have been held either in these or in any of the reported fatal cases of mumps, and in the absence of such unequivocal evidence it is impossible to affirm the existence of meningitis. In Munro's case—which was a very severe one and accompanied by a very high temperature (107·2°) and great delirious excitement with much prostration — although recovery took place it is stated that for a considerable time after the acute symptoms subsided the patient was excitable and also suffered from difficulty in walking; the gait was unsteady and incoördinate, the speech hesitating and impulsive, and agraphia was marked. This condition is certainly suggestive of cerebral and spinal meningitis, but cannot, I think, be pronounced conclusive. These cases seem to me to be much more closely related to those of acute rheumatism with hyperpyrexia and cerebral symptoms, and the affinity is strengthened by the fact that in some of these cases of mumps certain symptoms of acute rheumatism have been superadded; for example, in a case recorded by Charles Aitken,[26] an attack of mumps with orchitis was immediately followed by "a rather severe attack of rheumatic fever, with pains in the joints, but no cardiac mischief; this was almost immediately succeeded by a short attack of chorea." In Davis's case subsidence of orchitis was attended by general articular rheumatism, with much pain, but without fever. Endocardial murmurs developed in the course of Appleyard's case—a severe one with very high temperature though in this case there may have been pre-existing valvular disease. Metastatic endocarditis was also the chief feature of one of the set of cases reported by Haldeman,[27] which recovered, however, and there was thought to be endocarditis in Gillet's case also, which, as has been already mentioned, ended in sudden death. Thus instead of ascribing any cases of this group to meningitis I think it far more probable—almost certain, indeed—that the grave symptoms are really those of cerebral irritation due to some kind of blood poison which is developed in the course of the disease, especially about the period at which inflammation settles on the testes.

B.—A similar sort of explanation probably applies to this class also. Resembling the former group in the presence of delirium, it differs in the fact that the temperature and febrile symptoms are generally less high; the delirium begins about the same period as in the former class or when the orchitis is disappearing, but does not subside with the natural subsidence of the disease being prolonged, often for a month or two, in the form of insanity either mania or melancholia. Cases of this sort have been recorded—one by Radcliffe[28] and three (one of whom was a woman, but it is not stated whether her sexual organs were affected) by Van Bibber.[29] All these cases recovered.

This occasional sequence of insanity constitutes another point of affinity to *acute* rheumatism.

C.—On the other hand, this explanation will scarcely cover all cases of the cerebral symptoms of mumps. In an able paper by Lannois and Lemoine (Des Manifestations Méningitiques et Cérébrales des Oreillons),[30] three cases are described (one observed by themselves, the other two quoted from Sorel and Janson-Zuède respectively) which presented definite and persistent paralyses, which cannot well be ascribed to nervous debility following the disease. In the first case—in which, by the way, there is no mention of orchitis—there suddenly supervened after the parotid swellings had subsided in the usual way a condition of coma, with right hemiplegia, and hemianæsthesia, as well as conjugate deviation of the eyes, unilateral paralysis of the face and tongue, and aphasia. The hemiplegia and aphasia lasted for some time, but ultimately recovery took place. A closely similar case is reported by Hitchcock.[31] The patient was a woman who, after the subsidence of a severe febrile attack of mumps, was suddenly seized on the eleventh day with cerebral disturbance and vomiting, soon succeeded by coma, paralysis of the right arm, and convulsions. In a month's time the paralysis disappeared and the patient recovered. In Sorel's case (Orchite ourlienne atrophiante; complications cérébrales; aphasie légère mais prolongée)[32] the temperature reached 107° F. while the orchitis lasted, and the attack was severe. Convalescence was gradual, and attended by a variety of aphasia. In Janson-Zuède's case[33] furious delirium supervened during the orchitis and was accompanied by aphasia and paralysis of the right arm as well as anæsthesia and a slow pulse. The patient partially recovered, however. Partial paralysis of the arms is mentioned also in one of Haldeman's fatal cases. The explanation offered by Lannois and Lemoine of the whole class of cases of cerebral complications of mumps is that the cause is probably active hyperæmia of the meninges in the slighter cases, and in the more severe ones, in which some degree of actual paralysis occurs, the hyperæmia is more intense, extending more deeply and damaging the surface of the brain itself. This hypothesis may possibly be the true one, yet it is very doubtful. It seems much more probable from the histories that the paralysis is due to some accident, such as hæmorrhage or embolism, rather than to an inflammatory process. I think it is most likely that the real condition of these cases is embolism, for there is corroborative evidence in certain cases which show a tendency to thrombosis in mumps. Gillet's case, already quoted, was probably fatal by embolism; but instead of its fatal end being brought about by cardiac thrombosis and embolism of a cerebral artery, I would suggest that it might be due to venous thrombosis and embolism of the pulmonary artery. I have seen sudden death happen in an exactly similar way from pulmonary embolism in a case of cancer of the tongue; the cases of endocarditis related by Appleyard and Haldeman also mark a liability to embolism. There is also a remarkable case narrated by Logan (Metastasis in parotitis)[34] in which, about three weeks after the onset of an attack of mumps affecting the parotids and testes, phlebitis set in, first in the left lower limb, involving the

femoral, popliteal, and one-third of the anterior and posterior tibial veins, then the left upper limb, involving the jugular, subclavian, brachial, and part of the ulnar veins; after this, the right lower limb was involved as the left had been, Thus the main veins of three limbs were successively plugged. In each of these attacks of phlebitis the inflammation seemed to start from one of the glands which had been involved. In such a condition it is easy to see what a liability to embolism there must be. This patient recovered. However, in the absence of necropsies on fatal cases it is impossible to do more than conjecture. It is a matter that requires more light to be thrown upon it, and it is with a view to calling attention to the subject that these suggestions are offered.

A last word may be said about treatment. As has been already said, nearly all cases recover, and therefore the prognosis is good. But in the way of giving relief and promoting cure in the feverish, delirious patients, I think no measures have proved so effectual as the administration of cooling, diaphoretic, and aperient medicines, such as were exhibited in the case I have narrated. Narcotics should, I think, be avoided. It was also worthy of note that in a large proportion of the cases here collected the grave symptoms followed and were apparently induced by carelessness and exposure to cold, &c., while recovering from a simple attack of mumps. It may, therefore, be of importance to exercise prudence and to take necessary precautions during convalescence from the disease, especially in the case of adults.

Elizabeth-street, S.W.

ON THE PATHOLOGY AND TREATMENT OF CHILBLAINS.

BY A. E. WRIGHT, M.D. DUBL.,
PROFESSOR OF PATHOLOGY, ARMY MEDICAL SCHOOL, NETLEY.

I HAVE in a recent issue of THE LANCET[1] dealt with the general question of "serous hæmorrhage" (i.e., of increased transudation of the blood fluids into the tissues), and I have pointed out (*a*) that this condition is very often dependent upon a defect of blood-coagulability, and (*b*) that serous hæmorrhage can to a large extent be controlled by increasing the coagulability of the blood. I had in previous papers dealt with this question of serous hæmorrhage in its special relation to urticaria, and had demonstrated not only that urticaria is very often dependent upon a condition of defective blood-coagulability, but also that this affection can often be relieved in a very striking manner by increasing the patient's blood-coagulability. I propose in this paper to adduce evidence to show that what holds true of urticaria holds true also of that very familiar form of serous hæmatoma which we denote by the name "chilblain."

Association of chilblains with a condition of defective blood-coagulability.—I have investigated the condition of blood-coagulability in ten cases of chilblains. *Two* of these cases were cases of aggravated chilblains occurring in adult males. The blood-coagulation times of these patients were respectively *nine minutes*, and *nine and a quarter minutes*. *Four* of these cases were cases of aggravated chilblains occurring in adult females. The respective blood-coagulation times of these cases were respectively *thirteen minutes*, *eleven minutes*, *eight and three-quarter minutes*, and *seven and a half minutes*. Lastly, *four* of these ten cases were mild cases of chilblains occurring in schoolboys. The coagulation times of these cases were respectively *eleven minutes*, *nine and a quarter minutes*, *seven and three-quarter minutes*, and *four and a half minutes*.[2] It is obvious, therefore, when we consider that the normal blood-coagulation time varies between *three and four minutes*, that in all these cases of chilblains, with the exception of the last case, were associated with a very notable defect of blood-coagulability. This fact stands in relation with certain other facts which obtrude themselves more directly upon the clinician's attention. These facts are—(*a*) the superior liability of children to chilblains; (*b*) the fact that chilblains are prone to occur in persons who give a history either of nose-bleeding or of urticaria; (*c*) the occurrence of chilblains in persons who are characterised by a lymphatic habit of body; (*d*) the not unfrequent occurrence of chilblains in persons who are the subjects of malarial cachexia; and (*e*) the not unfrequent occurrence of chilblains in hæmophilic families. We may briefly consider each of these predisposing causes.

Childhood.—The notorious liability of children to chilblains is no doubt in part referable to the fact that the influence of cold makes itself felt more upon the relatively small extremities of the child than upon the relatively large extremities of the adult. Another probable factor in the etiology is the fact that the lime salts upon which the coagulability of the blood depends are in the growing child being continually removed from the blood in order that they may be deposited in the bones.

Predisposition to urticaria and epistaxis.—There is an obvious relation between the predisposition to epistaxis, the predisposition to urticaria, and the predisposition to chilblains, inasmuch as these predispositions have been shown to depend upon a defect of blood-coagulability. In two cases which have recently come under my observation I have seen urticaria alternate with chilblains. Both these forms of serous hæmorrhage were apparently brought on in susceptible patients by exposure to cold.

Lymphatic habit of body.—We shall understand the relation between the lymphatic constitution and a predisposition to chilblains if we consider, first, that the essence of the lymphatic constitution is to be found in a water-logging of the tissues which is dependent upon an excessive transudation of lymph; secondly, that it will require only a very slight increase of transudation to convert such a water-logged condition of the tissues into perfectly definite hæmatomata such as we see in chilblains; and thirdly, that in all probability both chilblains and the water-logged condition of the tissues which we meet with in the lymphatic patient are ultimately referable to a defect of blood-coagulability.[3]

Malarial cachexia.—The subjects of malarial cachexia are not unfrequently also the subjects of chilblains. It is even possible, as I am assured by a medical officer who has experience of the truth of this fact in his own person, to suffer from chilblains on the West Coast of Africa after a severe attack of malarial fever. This liability of the malarious subject to chilblains is in absolute conformity with the fact that the blood of patients, who are the subjects of malarial cachexia, is characterised by a defect of blood-coagulability which is dependent upon a great paucity of white blood corpuscles,[4] especially of polynuclear white blood corpuscles.

Hæmophilic constitution.—I have pointed out in previous papers that the chilblains are of very frequent occurrence in hæmophilic families. This stands in connexion with the fact that hæmophilic blood is, as I have previously shown, characterised by an extreme defect of blood-coagulability which is dependent upon an extreme and hereditary paucity[5] of white blood corpuscles and, in particular, upon a paucity of polynuclear white blood corpuscles.

Treatment of chilblains.—In view of the etiological facts which are thus disclosed, the obvious indication for treatment in a case of chilblains is to take steps to augment the patient's blood-coagulability. In conformity with these indications I placed my patients upon a regimen of calcium chloride (after duly cautioning them against lowering their blood-coagulability by the ingestion of sour fruits, alcohol, or excessive quantities of fluid[6]). Of the 8 cases which are particularised below, six cases (Cases 1, 4, 5, 6, 7, and 8)

[1] THE LANCET, Sept. 19th, 1896.

[2] All these coagulation estimations were made with coagulation-tubes of 0·25 mm. internal diameter, obtained from Mr. A. E. Dean, jun., 73, Hatton-garden, London, E.C. In order to bring the tubes to the standard temperature of 18·5° C. (half blood heat), their butt-ends were first fitted with indiarubber caps, and they were then immersed (point upwards) into a tumbler two-thirds full of water at that temperature. After filling in with blood the tubes were again immersed (this time point downwards and without caps) in the tumbler of water.

[3] It is customary to impute the liability of the lymphatic patient to chilblains to the patient's bad circulation. But in many cases it is, in all probability, not the bad circulation which produces the œdema. It is rather the œdema which impedes the circulation of the blood in the tissues, especially in the tissues of the extremities.

[4] There may in malarial cachexia be as few as 400 white blood corpuscles in the c.mm. of blood.

[5] It is unusual to find more than from 4000 to 5000 white blood corpuscles in the c.mm. of hæmophilic blood, and as few as 35 per cent. of these may be polynuclear white blood corpuscles.

[6] I find that it is quite unnecessary to caution a lymphatic patient against ingesting excessive quantities of fluid, for the typical lymphatic patient, owing probably to that water-logging of the tissues which has been referred to above, is aparently never thirsty. The lymphatic young woman contrasts markedly in this respect with the wizened elderly woman, whose dry tissues seem to require to be irrigated with perpetual draughts of tea.

Hosted by Google

responded to this treatment with a marked increase of blood-coagulability. These cases were all completely cured as soon as a sufficient augmentation of coagulability had been achieved. In one of the remaining cases (Case 2) no good whatever resulted from the treatment. In this case, owing perhaps to the maladjustment of the dose of calcium chloride, no augmentation of coagulability was obtained. Finally, in Case 3 only transient and uncertain amelioration was obtained from the treatment. And here, again, only a very transient augmentation of coagulability was obtained.

CASE 1.—The patient was a woman aged twenty-seven years. She suffered every winter from very bad chilblains. On Oct. 31st, 1896, the mean temperature for the day was 38·2° F. The patient's hands were very red and swollen and the skin had a very glazed appearance, especially over the proximal joints of the fingers. The blood-coagulation time was *thirteen minutes*.[7] Twenty grains (1·3 gramme) of calcium chloride cryst.[8] were prescribed night and morning. On Nov. 11th the mean temperature for the day was 44·2° F. The chilblains were almost gone. The skin was no longer glazed, but a certain amount of redness and thickening still persisted. Calcium chloride was ordered to be continued in the same doses. The blood-coagulation time was *nine minutes*.[9] On Nov. 3rd the mean temperature for the day was 40·2°. No notable change occurred in the condition of the hands since the day previous. The blood-coagulation time was *eight minutes, forty-five seconds*. Calcium chloride was ordered to be continued in the same doses until the chilblains absolutely disappeared. The treatment was to be resumed as soon as the chilblains threatened to reappear. On Nov. 11th the mean temperature for the day was 35·1°. The chilblains absolutely disappeared. The fingers are now quite thin and white.

CASE 2.—The patient was a man aged thirty-five years. He suffered very severely from chilblains every winter and was very subject to attacks of urticaria every summer. On Nov. 3rd, 1896, the mean temperature for the day was 40·2° F. Every finger on both hands was markedly stiff and œdematous. The skin over the fingers was reddened and glazed. There was, in addition to the chilblains on the fingers, a tense and painful serous hæmatoma on the hypothenar margin of the right hand. The blood-coagulation time was *nine minutes, twenty seconds*. Forty grains (2·6 grammes) of calcium chloride cryst. at night followed by a 20-grain (1·3 gramme) dose on rising and by another 20-grain dose at midday was prescribed. The mean temperature for the day was 36 2° F. On the 11th the patient reported that the chilblains were better yesterday and that they were as bad as ever to-day. The appearance of the hands bore out the patient's statements. The blood-coagulation time was *ten minutes ten seconds*. Twenty grains (1·3 gramme) of calcium chloride cryst. were ordered three times a day. Owing to a misunderstanding, the patient, however, now took only 20 grains at night and another 20 grains in the morning. On the 9th the mean temperature for the day was 39·1°. The chilblains were said to be no better; they looked rather worse than they were before treatment was begun. The blood-coagulation time was *twelve minutes, thirty seconds*. Owing to external circumstances the observations on this case were now abandoned.

CASE 3.—The patient was a woman aged twenty-five years. She was lymphatic-looking and had suffered severely from chilblains every winter since she was an infant; she had also suffered severely from epistaxis. She had for some time past been taking calcium chloride (30 grains) twice a day somewhat irregularly and with little result. On the whole, however, the chilblains were said to have improved somewhat under the influence of the drug. On Nov. 11th, 1896, the mean temperature for the day was 44·2° F. The fingers were still somewhat swollen and the skin was red and glazed. The blood-coagulation time was *eight minutes, forty-five seconds*. Thirty grains (2 grammes) of calcium chloride cryst. twice a day were prescribed. On the 5th the mean temperature for the day was 41·1° F. There was no appreciable change in the chilblains. The blood coagulation-time was *six minutes, twenty seconds*. Thirty grains (2 grammes) of calcium chloride cryst. three times a day were prescribed. On the 7th the mean temperature for the day was 32·2°. The chilblains were said to be somewhat better. The blood-coagulation time was *ten minutes*. The treatment was continued for some days longer without producing any definite result. It was then abandoned.

CASE 4.—The patient was a woman, aged twenty-seven years, and was a very lymphatic-looking subject; she had suffered very severely from chilblains every winter since her infancy. On Nov. 9th the mean temperature for the day was 36·1° F. The patient's hands presented a very curious parti-coloured appearance, the hand from the wrist to the knuckles being very pallid and all below the knuckles being of a bright boiled lobster colour. The fingers were very swollen and stiff. The blood-coagulation time was *eleven minutes*. Twenty grains (1·3 gramme) of calcium chloride cryst. three times a day were prescribed. This treatment was continued for a week without any marked change either in the blood coagulability or in the chilblains. The patient, however, insisted that she was better and suffered less from itching. After this time the treatment was, owing to external circumstances, very irregularly carried out. On Dec. 21st the mean temperature for the day was 32·2°. The patient presented herself again for treatment. The hands were much in the same condition as before, but were somewhat less swollen. The blood-coagulation time was *eight minutes, forty seconds*. Twelve grains (0·8 gramme) of calcium chloride desicc. three times a day were prescribed. On the 22nd the mean temperature for the day was 32·2°. The fingers appeared not to be so congested. The blood-coagulation time was *seven minutes, thirty-five seconds*. Eighteen grains (1·2 gramme) of calcium chloride desicc. three times a day were prescribed. On the 23rd the mean temperature for the day was 35·2°. The chilblains were said to be rather worse. There was no observable change in the condition of the hands. The blood-coagulation time was *seven minutes, forty-five seconds*. Nine grains (circ. 0·6 gramme) of calcium chloride desicc. three times a day were prescribed. On the 26th the mean temperature for the day was 41·2°. The chilblains were very markedly better. The blood-coagulation time was *six minutes, twenty-five seconds*. Nine grains of calcium chloride desicc. three times a day were prescribed. On the 28th the mean temperature for the day was 43·2°. The chilblains were now practically well. Only a very little redness and a trace of œdema remained. The blood-coagulation time was *six minutes, twenty seconds*. Six grains of calcium chloride desicc. three times a day were prescribed. On the 30th the mean temperature for the day was 39·3°. The fingers had now become perfectly thin and redness had to a very great extent disappeared. The patient expressed herself as perfectly well. The blood-coagulation time was *six minutes*. Six grains of calcium chloride desicc. three times a day till all redness had disappeared were prescribed. Treatment was then to be discontinued and to be resumed on the first re-appearance of the chilblains.

CASE 5.—The patient was a boy aged eleven years. On Nov. 30th, 1896, the mean temperature for the day was 33·1° F. He had chilblains on the feet The little toes on both feet were found to be œdematous and congested. The blood-coagulation time was *eleven minutes*. Fifteen grains (1 gramme) of calcium chloride cryst. morning and evening were prescribed. On Dec. 2nd the mean temperature for the day was 42·1°. The chilblains had quite gone. The blood-coagulation-time was *five minutes, fifteen seconds*.

CASE 6.—The patient was a man aged twenty-two years. He had suffered severely from chilblains every winter. On Dec. 17th, 1896, he had extremely swollen and livid hands; the skin over the chilblains was everywhere peeling off, leaving deep and painful chaps. In addition to the chilblains on the fingers there was a large, tense chilblain of about the size of a walnut over the hypothenar margin of the hand. The blood coagulation time was *nine minutes, five seconds*. Twenty-three grains (1·5 gramme) of calcium chloride cryst. three times a day were prescribed. On the 18th the mean temperature for the day was 30 2° F. The chilblains were less swollen. Itching was said to have been much better than on the previous night. The blood-coagulation time was *eight minutes*. On the 19th the mean temperature for the day was 30·5°. The chilblains were much the same in appearance. The

[7] It is a point worth noting that in connexion with the diminution of blood-coagulability a patient who bleeds freely from the pin-prick which is made in the finger is a patient whose blood-coagulability is considerably abnormal. In such a case it will be unnecessary to examine the condition of the contents of the first capillary tube until an interval of at least from five to six minutes has elapsed.

[8] It is important in ordering calcium chloride to specify either calcium chloride cryst. or calcium chloride desicc., for the first of these preparations is exactly half the strength of the second. I have invariably, unless where otherwise specified in my papers, employed calcium chloride cryst.

[9] In this and in all the following cases the determinations of blood-coagulability were, in order to secure accuracy, made almost at exactly the same hours on successive days.

Hosted by Google

itching is said to have been nearly as bad as before. The blood-coagulation time was *eight minutes, twenty seconds*. Fifteen grains (1 gramme) of calcium chloride cryst. three times a day were prescribed. On the 20th the mean daily temperature was 34·1°. The fingers were no longer so swollen. The skin over the chilblains had become quite loose and wrinkled. This was particularly noticeable over the hypothenar margin of the hand. There was no itching whatever the previous night. The blood-coagulation time was *four minutes, ten seconds*. Ten grains (0·6 gramme) of calcium chloride cryst. three times a day were prescribed. On the 21st the mean temperature for the day was 32 2°. There was more itching the previous night; the chilblains were decidedly tenser. The blood-coagulation time was *ten minutes*. Fifteen grains (1 gramme) of calcium chloride cryst. three times a day were prescribed. On the 22nd there had been very little itching the previous night and the chilblains looked very much better. The blood-coagulation time was five minutes, forty-five seconds. Eighteen grains (1·2 gramme) of calcium chloride cryst. three times a day were prescribed. On the 24th the mean daily temperature was 34·3°. The chilblains were almost quite well. There was now no swelling and very little lividity to be seen. The blood-coagulation time was *six minutes*. The patient considered himself perfectly well and considered it unnecessary to pursue the treatment.

CASE 7.—The patient was a boy aged eleven years. On Dec. 19th, 1896, the mean temperature for the day was 30·5° F. He had chilblains on the feet. There was not much to be made out on inspection except a little swelling and lividity. Great complaints were, however, made of intolerable itchiness, and the father said that the boy cried every morning from the pain when he was putting on his boots. The blood-coagulation time was *seven minutes, forty-five seconds*. Ten grains (0·6 gramme) of calcium chloride cryst. three times a day were prescribed. On the 20th the mean temperature for the day was 34·1°. The chilblains were said to be much better and there was no pain on putting on his boots. The blood-coagulation time was *six minutes, fifteen seconds*. Ten grains (0·6 gramme) of calcium chloride cryst. three times a day were prescribed. On the 21st the mean temperature for the day was 32·2°. There had been no further pain or itching. The blood-coagulation time was *six minutes, thirty seconds*; 7·5 grains (0·5 gramme) of calcium chloride cryst. three times a day were given. On the 22nd the mean temperature for the day was 35·2°. The chilblains had absolutely disappeared. The blood-coagulation time was *four minutes, twenty seconds*.

CASE 8.—The patient was a boy aged eleven years. On Dec. 20th, 1896, the mean temperature for the day was 34·1° F. The chilblains on his feet looked very trifling, but great itching was complained of. The blood-coagulation time was *four minutes, thirty seconds*. Twelve grains (0·8 gramme) of calcium chloride cryst. three times a day were prescribed. On the 21st the mean temperature for the day was 32 2°. The chilblains were said to have been less itchy. The blood-coagulation time was *five minutes*. Six grains (0·3 gramme) of calcium chloride cryst. three times a day were prescribed. On the 22nd the mean temperature for the day was 35 2°. There was some itching last night. The blood-coagulation time was *five minutes, five seconds*. Twelve grains (0·75 gramme) of calcium chloride cryst. three times a day were prescribed. On the 23rd the mean temperature for the day was 35·2°. The chilblains were stated to be perfectly well. The blood-coagulation time was *four minutes*.

In conclusion, I would point out that the importance of the facts which have been put on record does not consist solely in the fact that calcium chloride has been shown to be a palliative for chilblains. It consists rather in the fact that these observations contribute to further establish the principle that serous hæmorrhages are often dependent upon a defect of blood-coagulability, and that they may be relieved or prevented in exactly the same way as actual hæmorrhages can be by augmenting the coagulability of the blood.

Netley.

MUNIFICENT GIFT TO THE LEEDS INFIRMARY.—An anonymous donor has given, through Messrs. Beckett and Co., the sum of £4000 to the Leeds General Infirmary. This munificent gift is offered on the distinct understanding that it is used for endowment and not for building purposes, and on this condition the treasurer of the infirmary has gratefully accepted the contribution.

CHOLERA IN PENANG (NOT WATER-BORNE).

NOTES ON MEDIA OF INFECTION, PERIOD OF INCUBATION, RESULTS OF QUARANTINING, ETC.

BY SURGEON-CAPTAIN F. SMITH, A.M.S.,
LATE ACTING HEALTH OFFICER, MUNICIPALITY OF PENANG.

DURING the year 1895 cholera prevailed in Singapore, which is only some thirty-six hours' steam from Penang. The disease was several times imported from the former to the latter place among the indentured Chinese coolies who are under Government surveillance; thus a specially favourable opportunity of tracing the history of the cases from beginning to end was afforded. So much has been written and said about "water-borne cholera" of late that other media of infection are in danger of being overlooked, and it is worth noting that experience of the disease in Penang, where the water-supply is excellent, seems to show clearly enough that cholera may be spread about by human intercourse without the agency of water. It also teaches that the much-decried quarantine is *sometimes* effectual in preventing the dissemination of disease, and that the incubation stage—or rather the period between exposure to infection and the onset of illness—may be prolonged much beyond the five days' limit usually given.[1]

On July 29th, 1895, a Chinaman, who had just come direct from his ship to the office of the Protector of Chinese, was sent to hospital, when the disease was diagnosed as cholera. He was at once sent to the Hospital for Infectious Diseases, and the depôt containing the coolie passengers by the same ship was put in quarantine under a police guard. (This course was pursued in each Depôt in which cholera occurred subsequently or in which there were any coolies off a ship which had brought a cholera case.) Two more cases occurred among these men three days later and no more. About the same time a sick coolie sent direct from another Singapore ship to hospital was pronounced to be suffering from cholera. Owing to the above occurrences a five days' quarantine was imposed on vessels bringing coolies from Singapore. The owners of vessels were allowed to land their passengers on Quarantine Island and go on instead of waiting in harbour. The s.s. *Hebe* did this three times, and on the third occasion cholera appeared among the coolie passengers landed by her; there were three cases, all being fatal. On Sept. 4th, five days after the last case had gone to hospital, the passengers were released. Some of the coolies went to Perak, a native State on the mainland, and on Sept. 9th one of them developed cholera. This was ten days after the last case on Quarantine Island and five days after leaving there. Quarantine Island, I should say, is a small island near Penang, used for a leper asylum and for quarantined passengers; it has no connexion with the hospital for infectious diseases which is on Penang Island.

On Sept. 7th the passengers of the s.s. *Ban Hin Guan* were landed on Quarantine Island and released after five clear days as no case had occurred. Most of the coolies went to the "Kia Heng" Depôt and the remainder to the "Sin Seng Hong Chan" Depôt. The morning after the release of these passengers, most of whom were coolies, one of them had cholera in the "Kia Heng" coolie depôt, more than six days after leaving Singapore. The depôt was promptly quarantined. Two days later there were two more cases, and then the disease stopped as far as this depôt was concerned. In the meantime the *Calypso* had come in, and owing to the Government at headquarters (Singapore) having cancelled the order for quarantining Singapore ships just after the arrival of the *Ban Hin Guan*, the coolie passengers of the *Calypso* went direct to the depôt, and on the sixth day from leaving Singapore one of the coolies had cholera in the "Ap Dho" depôt and another in the same place four days later. Here the disease ends in the "Ap Dho" depôt. On Sept. 21st the s.s. *Calypso* again arrived from Singapore with coolies, who were put in the "Sin Seng Hong Chan" depôt, in which, as before stated, there were a few of the men of the *Ban Hin Guan*. This being the seventh day since the last case among the men of the *Ban Hin Guan*, and there

[1] Vide Quain's Dictionary and other works.

Hosted by Google

being a dearth of room elsewhere, it was considered safe to allow newly-arrived coolies to enter this depôt in which there had been no cholera. On the same day after the order for the opening of this depôt had been issued, but an hour or two before the entry of the men of the s.s. *Calypso*, a *Ban Hin Guan* man in this depôt was sent to the General Hospital among the ordinary sick and the disease proved to be cholera; it was followed by another case in the evening. The depôt was quarantined, and as the men of the *Calypso* had already mixed freely with the others it was considered unsafe to let them out, and they were therefore included in the quarantine. Three days later another man from the *Ban Hin Guan* and one from the *Calypso* had cholera, and on the 26th another man from the *Ban Hin Guan*. The man from the *Calypso* may have contracted the disease in Singapore, or on the ship, or in the depôt, but how about the first case from the *Ban Hin Guan* in this depôt? He had been more than fifteen days away from Singapore. The depôts are always closed and privately guarded to prevent the escape of the coolies with their advanced pay, so there could have been no inter-communication; they are entirely separate establishments. For convenience of employers of labour they are all in the same locality, but there are several business and dwelling houses, in none of which cholera occurred between this depôt and the "Kia Heng" and other depôts. From the readiness with which the people report small-pox, chicken-pox, &c., it may be assumed that they would not conceal cases of the much-dreaded "Muntah Cherit" (cholera). It might be suggested that this man contracted the disease on Quarantine Island, but even so it would make the incubation period more than ten days. Strict precautions were taken in the depôts and each patient was promptly removed to the hospital for infectious diseases with all his belongings, after which his room was disinfected and whitewashed. The pail system is in vogue for excreta; the pails are emptied daily. After each case the pails were taken away and new ones supplied, and the seats, walls, &c., cleaned and disinfected. The depôt was scrupulously clean, and the only water in the place was the regular municipal pipe-supply, such as is used by the 92,000 inhabitants who had no cholera. The basement is tiled and somewhat damp from over-much washing down, and here the men bathe daily by pouring water over themselves standing. The water off their bodies runs away at once into the open drain outside in the street. There is in the bathing-place a slight fæcal odour from the latrines. The upper rooms of the depôts are over-crowded and the inmates never get out night or day until they leave for the estates; the coolies make matters worse by crowding together in one or two rooms to play cards, and in the result the air is perceptibly impure and laden with the products of respiration. Acting on the supposition that there was something wrong with the depôt itself (inasmuch as isolation of sick and disinfection of rooms, which had appeared to be successful in other depôts built on the same pattern did not arrest the disease), it was decided to empty it, and on Sept. 28th the whole of the coolies (ninety in number), of whom it should be noted that only thirteen were passengers from the *Ban Hin Guan*, were removed to Quarantine Island. The depôt was then thoroughly disinfected from roof to basement and re-occupied by fresh coolies, after which there were no more cases of cholera in it. The disease, however, did not immediately cease among the men who had been removed to Quarantine Island. On the 30th there were two cases—one a man from the *Ban Hin Guan* and one a man from the *Calypso*. Seven days later two more men from the *Calypso*, and on Oct. 11th another man from the *Calypso*. All five cases were fatal. This ended the outbreak.

It would have been better to have removed these coolies to some other place instead of the Quarantine Island, as we cannot now say whether they brought the disease with them from the "Sin Seng Hong Chen" depôt or contracted it from germs left on the island by the s.s. *Hebe* passengers. Every sanitary precaution, however, was taken by the colonial surgeon, who is confident that the disease was not contracted on Quarantine Island. The men had abundance of fresh air and exercise there. The water-supply is the same as that used by the adjacent leper asylum, in which there are over 500 lepers, among whom there was no cholera.

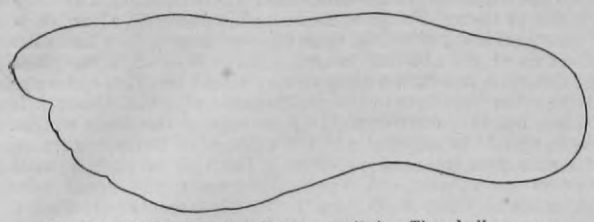
The first case among all four sets of passengers may be safely assumed to have been contracted in Singapore, though it is possible, of course, that the men of the *Ban Hin Guan* were infected on the quarantine island. The later ones are not easy to account for unless we suppose the disease was handed over from one man to another, and this is probably the correct view. The occurrence of the last five seems to show that the attacks were not due to any sanitary defects inherent in the "Sin Seng Hong Chan" depôt, unless they are to be looked upon as instances of prolonged incubation. It may also be taken as fairly conclusive that the cases were not water-borne, even if the Chinese drank water instead of the universal tea. The case for quarantine seems to be made out in the history above given. Had these men mixed with the dense Asiatic population, ignorant as they are of sanitary matters and living under worse conditions than the coolies, Penang might have suffered like the sister settlement. As to incubation and media of infection, it is clear that either the incubation in some of these cases was very long or the infective matter was carried about by the men for some time before it was inhaled, swallowed, or otherwise absorbed into the system. In this regard the first case in the "Sin Seng Hong Chan" depôt seems most convincing; the period cannot be made less than ten days, and was most probably fifteen. The disease is not likely to have been conveyed by food, inasmuch as all the meals are served hot from a separate building to which the coolies have no access. Food is not kept in the coolies' rooms for flies from the latrines to settle on. The Chinese do not eat with their hands, like the Mahomedan Malays, but use spoons and chopsticks.

On the whole it would seem that if the disease was not in all the cases contracted in Singapore the infection must have been aerial; but whether by germs emanating from the bodies of the men or shaken off their clothes or hair, or given off by the fæces or vomit, is entirely a matter of speculation.

ON VARIOUS FORMS OF TALIPES AS DEPICTED BY X RAYS.[1]

BY RICHARD BARWELL, F.R.C.S. ENG.,
CONSULTING SURGEON TO CHARING-CROSS HOSPITAL.

(Continued from p. 1812, vol. ii., 1896.)



FLAT-FOOT is a deformity which, if further advanced, is termed valgus; it is characterised by loss, more or less complete, of the transverse and longitudinal arches of the foot, the sole being so flattened that the whole of it comes to the ground. If the sole of a well-formed foot be wetted with some coloured fluid and placed on a sheet of paper the impression left by such contact is as follows: the heel and the pad just behind the toes (thenar and hypothenar eminences) form the larger parts of the impression; they are connected by a narrower portion corresponding to the outer border of the waist of the foot. The outline of this narrower part is on the outer side convex and on the inner margin strongly concave; indeed, it is as though a semicircular piece were punched out of the diagram, the gap representing the place where, on account of its normal arched construction, the sole does not come to the ground. If in the same manner a print of a flat or valgous foot be made the impression presents no such gap, for the whole breadth of the sole, at the waist as elsewhere, comes in contact with, and makes its mark on, the paper. Moreover, the outline of both borders is changed: the outer one is no longer convex, but sharply concave; the inner one convex, presenting a considerable projection opposite the most hollow portion of the outer margin. Indeed, the words concave and convex hardly describe the form, for in front of, and behind, the medio-tarsus both halves of the foot are deflected outwards; therefore there is at either extremity of that joint what may be described as a rounded-off angle—at the outer margin an entering, at the inner a salient one. These are readily perceptible if the observer place his head in front of the erect patient's waist and look perpendicularly down on the naked foot. Or if he wish, as is desirable, to keep a record of the condition, he may, letting the patient stand on a sheet of paper, trace the outline with a sufficiently long cedar pencil. In this way was obtained the diagram here given (Fig. 12), the patient being directed to throw as much of the body weight as possible upon the distorted foot. The entering angle corresponds to the calcaneo-cuboid joint, the salient one to the head of the astragalus and to the

[1] The skiagrams were taken by Mr. Sydney Rowland, late Shuter Scholar, St. Bartholomew's Hospital.

Hosted by Google

scaphoid. Combined with this double abduction is outward rotation of both halves of the foot, a combination which, as a little reflection will show, must destroy both longitudinal and transverse arches and bring the bones forming the inner extremity of the medio-tarsal joint to the ground; the mechanism of this mal-posture will be explained in the sequel. The abduction, outer rotation, and the thereby conditioned yielding of the arch cause such projection of the head of the astragalus and of the scaphoid that those two bones are plainly visible through

FIG. 12.

Tracing of flat-foot (medium severity). The hallux was valgous, but held in position during tracing.

the skin and other soft parts, as in the annexed photogram. It will be observed that the inner malleolus is less marked than in a normal foot, being somewhat obscured by the bulging of parts below. This bulging forms a rather broad line of rounded eminence, traceable downwards and forwards from near the tip of the malleolus in a direction of a right angle and a half (135°) to the axis of the leg. A little closer inspection or palpation will show that it really consists of two rounded projections separated by a space of lesser prominence; the posterior of these belongs to the astragalus and the anterior is the upper inner corner of the scaphoid (not the tuberosity). The inner lower border of the foot forms a line that is very nearly straight; it is in contact throughout its whole length with the surface on which it stands. The upper outline, that of the instep, is also nearly straight, or rather when viewed quite from the side—that is, by an eye on the same horizontal level—it forms a concave line, hollow according to the severity of the case. The whole foot is lengthened by straightening out of the arch, the heel projects abnormally backward, and the anterior segment forward. In a large proportion of cases the anterior tibial tendon is unduly prominent, or even if not visibly so it frequently, as also the posterior, may be felt as a tight cord beneath the skin. At all the metatarso-phalangeal joints the toes are somewhat flexed,[2] most markedly the hallux, which is also usually thrown outwards (valgous), causing the second to lie over, or, as in this case, mounting above, that toe. I have not seen any instances of adduction of the metatarsus on the tarsus as described and figured by Rediard,[3] but I have more than once found it abducted.

FIG. 13.

Photogram of flat-foot (medium severity). Hallux valgus.

FIG. 14.

Skiagram of foot shown in previous figure.

In taking a skiagram of a part in which several bones lying one behind the other intercept the x rays the shadows

[2] This flexion is produced by tightening of the plantar fascia due to straightening out of the arch.

[3] Mr. Walsham (Deformities of the Foot) reproduces Rediard's figure, but says he has not met with the condition.

Hosted by Google

so produced are superimposed; they become thus somewhat intermingled, and a little diligence must be used in their interpretation. Such difficulties have already been encountered in my former illustrations and they recur in the annexed figure. (Fig. 14.) A little assistance, therefore, may aid the reader to differentiate the various bones. The three cuneiforms cannot be distinguished from each other; their shadows coalesce and overlap, but by taking the base of the fifth metatarsal bone as a guide the anterior end of the cuboid can easily be perceived, and the bulk of the bone is not difficult to make out, though the shadow of the scaphoid is so mingled therewith that it seems desirable to indicate how the two are to be differentiated. The highest and the lowest shadow is thrown by the scaphoid, the upper surface of which is marked, being seen quite in profile as a straight, rather short line just anterior to the head of the astragalus; running down from the ends of this line the back and front edges of the shadow diverge somewhat, then converge again, and coming together each in a crescentic curve, form the margins of the shade thrown by the tuberosity. The shadow of this part is of rather a light tone and is the lowest projection in the middle of the sole. The cuboid marks out a quadrilateral figure, the long axis being at right angles to that of the scaphoid; its hinder end abuts on the os calcis and partially overlaps the neck of the astragalus; the front one is to some extent concealed by the base of the fifth metatarsal bone. The upper and lower margins of the shadow are nearly horizontal, and cross, therefore, almost at right angles the back and front limiting lines of the scaphoid. The lower margin of the cuboid is pretty deeply notched, marking the outer end of the peroneal groove.

We may now go on to examine the bones. The whole astragalus, more especially the neck, is short. Probably a certain allowance must be made for the foreshortening due to abduction, yet this can only account for a small amount of the stunted shape. Moreover, the neck is bent upward. I would ask the reader to compare this plate with Fig. 2, a normal foot, and with Fig. 1, an equinous foot,[4] in order to get an idea of these changes. The os calcis is also somewhat abbreviated and its greater process is likewise deflected upward. The upper surface of the scaphoid is short from before backward. I find, by measuring a number of bones, that the proportion between the length from above down and the antero-posterior breadth of that surface is as 24 : 10. If the dimensions of this bone, as seen in the skiagram, were in the same ratio the upper edge of the shadow should be 5·8, whereas it is only 4. It has been shortened by pressure due to straightening out of the arch, or perhaps the sentence might be put thus. "As the crown of the bridge has slowly subsided the material of its keystone has been compressed." This view of the foot can only indicate, not distinctly show, the abduction of anterior and posterior halves above described; the rotation, however, is distinct, for on looking straight on the outside of a well-formed foot, the eye being on the same level, one should see, on account of its obliquity, a good deal of the dorsum, not merely the edge, as in the skiagram. In more severe cases this rotation is often sufficient to bring the external surface of the calcaneum in contact with the outer malleolus; indeed, this very nearly occurred with the extremity here shown when a certain amount of weight was thrown on the foot; but in that position the patient could not remain still sufficiently long; therefore, the skiagram had to be taken recumbent, otherwise the arch would have appeared much flatter and the tuberosity of the scaphoid would have projected still further into the sole.

It is thus abundantly clear that flat-foot and valgus are due to rotation outward of the extremity, followed by abduction on each other of anterior and posterior halves. It remains now to elucidate the mechanism of these changes. The feet of new-born infants are nearly flat, for though the outer lies lower than the inner border of the sole, yet there is under the waist of the foot hardly any hollow. The condition must not, however, be accepted as a deformity, for congenital varus or flat-foot is rare; indeed, its occurrence as a pure deformity unmixed with either calcaneus or equinus is doubtful. The infantile form of foot may, it is true, persist into after life; such child or adolescent waddles somewhat on out-turned, low-instepped feet; this "splay-footedness" though ungraceful, hardly amounts to a deformity. But by far the more usual course of events, that on which the activity and deftness as well as the beauty of the foot depends, is that soon after its proper use begins the hitherto flat sole should develop a well-marked arch and the low instep a high, prominent curve. The normal and correct form is, therefore, due to station and progression; it is, as it were, a bye-product of function. Hence, as such performance is due to muscular effort, it follows that these efforts mould the foot into shape. The usual and accepted assumption is that the tibial muscles are the chief, or rather that they are the only agents in lifting the tarsal bones into an arch and in sustaining them there. But neither of those muscles is advantageously placed for such action; the anterior is inserted into the distal end of the cuneiform, where the arch is already declining towards its front buttress; the posterior, after bending round the malleolus, runs forward almost in a line with the axis of the anterior tarsus; neither is at all in the place or direction in which a sling or stay would be. These muscles have other functions in the performance of which the arch is aided, but they cannot possibly so oppose the body weight as to uphold it, especially if the astragalus begin to turn on its axis and its head to droop. But this is exactly what occurs in valgus, and very often, as in the figure here submitted, one finds both tibials vainly struggling against that tendency, more especially if the condition be recent and somewhat rapid in its development. In older cases those muscles give up the useless effort

FIG. 15.

Nascent flat-foot from excessive labour. Ineffectual effort of anterior tibial to uphold arch. (From Barwell on Clubfoot.)

and one finds them flaccid. Although, then, these muscles are unable to prevent rotation of the os calcis, and with it of the astragalus, and though there is no muscle inserted into either bone that can perform this office, yet nature has provided another method. Projecting from the inner side of the calcaneum is a remarkable shelf or buttress of bone, upon which reposes the head of the astragalus, and which is called its sustainer. Viewed either from the front or back this is seen to project from the side at about a right angle to the plane of the inner surface of the calcaneum; it lies, therefore, very far beyond the centre of gravity and the line of support. The slightest weight on that shelf, therefore, must, unless it were upheld, overthrow the whole bone. The sustentaculum can of, and by, itself sustain nothing. The lower surface of the process, however, is scored by a wide groove (the photogram represents it in shadow), in which runs the tendon of the flexor longus pollicis, the muscle which does the chief work in most strong movements of the foot, and which from its oblique position behind the leg bones is most advantageously placed. In rapid walking the body is urged forward by the great toe; even in standing its aid is called for, in running, leaping, dancing it is in full use, and each time it thus exerts its power it draws up and sustains that process of the os calcis, and through it the head of the astragalus and the arch of the foot. The real sustentaculum tali is the flexor longus pollicis muscle. Hence, when the infant walks, using its toe for balance and progression, the os calcis is turned a little on its outer side, the head of the astragalus is lifted, and the arch of the sole and the prominent curve of the instep become duly formed. But certain conditions may interfere with the due performance of these functions—the child may from weakness of muscles either of back, of limbs, or of both, or from being put on his feet too

[4] THE LANCET, July 18th, 1896, pp. 160, 161. In both figures referred to in the text the neck of the bone is bent *down*.

Hosted by Google

early, find difficulty in balance and, therefore, considerably everts the foot, thus throwing the great toe out of work. Rickets by causing bends of the leg bones may render them short in comparison to the muscles, which then can hardly perform their duty. A little later in life the body weight of a fat or of a feeble child may overload the muscles, or (and this may occur long after childhood) he may be put to carry burdens beyond his strength; in either of these cases the pressure downward on the sustentaculum being greater than the flexor of the hallux can uphold the os calcis and astragalus must roll over. Furthermore, any circumstance

FIG. 16.

Os calcis (normal); posterior view.

which prevents the great toe performing its function and task causing the work to be done, not as it should be, by the last phalanx of the great toe, but by the head of its metatarsal bone, not only throws that flexor out of work, but calls forth improper over-action of other muscles especially of the peroneus longus.

One of the most common modes of thus destroying the use and value of the toe is the wearing of foot-gear coming to a point in the middle line and therefore compelling the great toe to lie over, or under, the second, where it cannot possibly fulfil its office. Many people, more especially many girls and young women, are thus sedulously and painfully engaged on the artificial production of flat-feet and of avoidable lameness.

(To be concluded.)

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

POISONING BY ANTIPYRIN; RECOVERY.

BY EDWIN WEBSTER, L.R.C.P. LOND., M.R.C.S. ENG.

A GIRL, aged nineteen years, whom I was attending for anæmia and who was taking Blaud's pills, came to me one morning quite recently complaining of headache. I prescribed for her a draught containing five grains of antipyrin, seven grains of bromide of potassium, one drachm of compound spirit of ammonia, and water to one ounce. In about ten minutes after taking it a hurried message was sent for me to go to see the patient, as she was taken seriously ill. On arrival at her home within a few minutes the following conditions were present—viz., cold shivers, severe and gasping dyspnœa; the face was swollen, especially about the eyes, and so much so as to prevent any possibility of opening them or of seeing, except with great difficulty, the pupil; and the body was covered with a bright red rash like scarlet fever and resembling that of urticaria, so that it presented weals which were of different sizes, from that of a small papule to some as large as five-shilling pieces. The temperature in the axilla was 97° F., and the pulse, which was very intermittent, was only 50. She complained of no pain. The tongue was very dry. The lips and general aspect were decidedly cyanotic. I immediately had the patient put to bed and administered stimulants in the shape of whisky, &c., with warmth, and medicinally I gave strychnine with digitalis. Notwithstanding all that was done she remained in this state for about eight hours, with the exception of the shivering, which passed off at the end of three hours. When beginning to rally the breathing, which at one time was so bad that I thought I should have to resort to artificial respiration, first showed improvement, and in about four hours later—except that the rash, which had become fainter, was present, together with a slight puffiness around the eyes—she seemed to be very little the worse for her experience. Next evening she was up and felt well, though somewhat weak, and the subsequent day she went about her work as usual. The rash took about thirty hours to finally disappear. This case, I consider, is interesting on account of the rapid onset of the attack and the quick appearance of the rash, together with the severe symptoms after such a moderate dose of antipyrin.

Brighton.

NOTE ON THE FAMILY HISTORY OF A PATIENT WITH ICHTHYOSIS.

BY W. G. WILLOUGHBY, M.D. LOND.,
MEDICAL OFFICER OF THE EASTBOURNE INFECTIOUS DISEASES HOSPITAL

A BOY having been sent into hospital under my charge suffering from diphtheria I noticed that he had ichthyosis badly and made inquiries as to the other members of the family and found as follows. The boy was one of a family of eight, in order thus: a boy, aged fifteen years, has ichthyosis; a boy, aged fourteen years, not anything wrong with his skin; a boy, aged twelve years, has ichthyosis; two girls, aged respectively ten years and nine years, nil; a boy, aged seven years, has ichthyosis; a girl, aged five years, nil; and a boy, aged five weeks, has ichthyosis. The parents and grand-parents of this family are quite free from skin disease, but the mother had heard that her father's mother had the disease. The mother of the family above mentioned has two sisters both free from skin disease, and one of these has children all free from skin disease. The mother's brothers, however, like her sons, are affected, and again one escapes the disease while the remainder, two in number, have ichthyosis. One of these two is married, but his seven children (boys as well as girls) are all free. His wife, however, who was said to have had a good healthy skin at the time of her marriage, has since developed the disease, according to my informant, her sister-in-law. She is only connected with the affected family by marriage.

It is interesting that in these two families the girls are quite free while the boys have the disease (with one exception in each family) and that though the girls of the senior family are free, while the boys are affected, it is through one of the free females that the disease has been passed on to the next generation of boys and not through the affected males.

Eastbourne.

A CASE OF SUPPURATING APPENDICITIS.

BY W. MACBAIN, M.D., C.M. ABERD.

MY excuse for reporting this case is its departure from the rule that free or repeated suppuration implies the obliteration of the appendix and consequent immunity from subsequent attacks. In a paper recently published by Dr. A. Woods[1] it is shown that this result occasionally occurs in cases of suppurative appendicitis when the abscess is opened and drained, the appendix not being removed, a recurrence having been met with in about 5 per cent. of the cases treated in this manner.

The patient is a robust, otherwise healthy man, aged about forty years, following an employment which necessitates occasional heavy manual exertion. He first came to me in June, 1895, suffering from an apparently mild attack of appendicitis. The case lingered for a couple of months without any serious relapse, but there were occasional slight

[1] Medical Record of Philadelphia, Aug. 22nd, 1896.

Hosted by Google

rises in temperature and a tumour formed about the size of an orange, which, however, gradually cleared up. On allowing him to leave his bed at the end of that time he at once relapsed and on my advice entered the Manchester Royal Infirmary. For three weeks after admission there was no rise of temperature or pain and he was permitted to get up, when his temperature at once increased to 104° F. Mr. Southam, under whose care the patient was, incised over the appendix, but such a copious flow of offensive pus welled out that it was not considered advisable to search for, and remove, the appendix, which was not seen; the abscess cavity was thoroughly washed out and a large drainage-tube was inserted. This was gradually shortened, and at the end of a month he was allowed to go home. Within a week of his return to work an abscess pointed at the old scar, and he was re-admitted to the infirmary, where the wound was freely opened, but the parts were so matted and densely adherent that the appendix could not be found, and Mr. Southam scraped out and drained the cavity, the wound healing fairly quickly. For nine months the patient continued to be in good health, but in October, 1896, an abscess again pointed, which I incised and drained, the man resuming work within a month. In the second week of this year he again appeared in my consulting-room, explaining that the old symptoms had returned but feeling disinclined to give up his employment the abscess had burst with copious discharge, and he himself cut five inches of drainage-tube, inserted it for four and a half inches, and dressed the wound with a pad of cotton-wool. He brought with him two small pieces of tissue which had come through the tube. These look reasonably like portions of the appendix, so there is a hope that this may prove the last of the series of relapses.

Cheetham-hill, Manchester.

A CASE OF ASPIRATION OF THE PERICARDIUM; LIFE PROLONGED EIGHT MONTHS.

BY JOSEPH JONES, M.B., CH.B. VICT.

THE patient, a girl fifteen years of age, suffered from mitral regurgitation left by acute rheumatism several years ago. On Jan. 6th, 1896, she was taken ill again with acute articular rheumatism and improved under the usual treatment until the 24th, when she became worse with great pain at the heart from pericarditis. She was blistered at the præcordium and put on salicylate of soda and morphia but got no better. On the 27th there was a loud see-saw murmur and the cardiac dulness extended to half an inch beyond the right sternal border, to the second intercostal space above, and to one and a half inches outside the left nipple line. The pain was somewhat easier. There was extreme dyspnœa, and the breath-sounds heard in the interscapular region were of a very loud and harsh bronchial character from pressure by the distended pericardium on the bronchi. This all grew worse until Feb. 2nd, the date of the operation, when the respiration was 80 to the minute, the pulse 160, and the temperature 99° F. The patient was quite dusky in the face and undoubtedly *in extremis*. After an exploratory puncture with a fine needle the medium-sized cannula of Dieulafoy's aspirator was used, having been previously sterilised by boiling in a 1 in 20 aqueous carbolic solution and subsequently kept in 1 in 10 carbolic acid in rectified spirit of wine. The skin was cleansed with the latter solution, and the trocar and cannula were inserted in the fourth intercostal space one and a half inches to the left of the sternum, in a direction downward and backward. Four and three-quarter fluid ounces of sherry-coloured serum (frothy, probably from air leaking in at the connexions of the aspirator) had been slowly withdrawn when a little blood came. Aspiration was then stopped and the cannula removed for fear of injuring the myocardium. The wound was covered with a piece of infirmary plaster. The dulness had diminished to practically its normal limits, and half an hour after the operation the patient was markedly better, the respiration being 60 and the pulse 140 per minute. The character of the breath-sounds could not be investigated just then as the patient was much too feeble to be troubled, but on the 9th they were much softer and quieter, the frequency being 36 per minute; the pulse was 108 and the temperature 98·5°. The patient continued to improve until the middle of June, when she was able to go to Southport for a few days. This appeared not to suit her for she commenced to be worse again, the heart dilated, and about the middle of August she developed anasarca. She died on Oct. 5th.

GREAT NORTHERN CENTRAL HOSPITAL.

RE-EXCISION OF ELBOW AFTER A LAPSE OF THIRTY-SIX YEARS.

(Under the care of Mr. PEYTON T. B. BEALE.)

IT is very unusual for surgeons to have an opportunity of re-excision of an elbow thirty-six years after it has been excised, nor is it usual for tuberculous disease to remain quiescent and to re-appear after so long a time in a patient who has performed hard manual labour all his life. Ollier has recorded a case in which he removed bone from the elbow on three occasions, at varying intervals, with a successful result, and there are several cases of a second resection with gratifying results known. In all probability the long interval which had elapsed between the two operations was most useful in adapting the parts to a second resection in this case. For the notes of the case we are indebted to Mr. H. R. Wadd.

A strongly built man, aged forty-seven years, was admitted to the Great Northern Central Hospital early in September, 1896. Thirty-six years ago—i.e., when the patient was eleven years of age—his left elbow-joint was excised at the Royal United Hospital, Bath, by Mr. Gore for tuberculous disease. A copy of the "operation register" shows the operation to have been performed on Dec. 15th, 1860. The result was entered as "cured." The patient said that the wound soon healed completely and he had an exceedingly good and useful limb—indeed, he has earned his living by hard manual work, lifting very heavy weights with the left arm, and he had not had the least pain or trouble in it until 1896. In June, 1896, the false joint at the left elbow became painful and swelled considerably; pus formed and it "burst," leaving two or three sinuses. On admission a very large abscess existed, which the house surgeon at once freely opened, and on inserting a probe found much bare bone. A few days after, on Sept. 15th, a long incision at the back of the elbow was made by Mr. Beale and about one and a half inches of the lower end of the humerus and at least an inch of the upper ends of the radius and ulna were removed. Mr. Beale, having dissected out as much of the diseased tissues as was possible, thoroughly scraped the intervening tissues. There was no doubt as to the disease of the bones being tuberculous. The wound was closed and tubes inserted and the limb put up on a straight splint so padded as to allow the limb to remain slightly flexed. It healed rapidly; the splint was discontinued on the sixth day and the patient was discharged on the twentieth day. On the twenty-eighth day the wound was completely healed, and the patient could lift a chair with ease with the left hand.

Remarks by Mr. BEALE.—The limb was put up very slightly flexed, because it was supposed that the patient would only have a little movement at the elbow, and seeing that the limb had been shortened about two inches at the first excision and again about three inches at the second excision I thought that this position of the limb would be the most useful for general work. The good result of the second excision is due to the excellent behaviour of the patient after the operation and to the fact that the house surgeon opened the abscess so promptly, thus putting the parts in a favourable state for excision. Had this not been done I feel sure amputation would have been the only

Hosted by Google

available treatment. I am greatly indebted to Mr. J. Macready for allowing me to have charge of the patient and to Mr. Rigg, house surgeon to the Royal United Hospital, Bath, for a copy of the operation register relating to the case.

BRISTOL ROYAL INFIRMARY.

THREE CASES OF ACTINOMYCOSIS.

(Under the care of Mr. GREIG SMITH, Mr. HARSANT, and Mr. BUSH.)

THREE cases of actinomycosis having occurred within six months at the Bristol Royal Infirmary the following record will be of interest. In two cases the correct diagnosis was made before operation; in each of these the history was very clear and the signs typical. In the third case the diagnosis was made on the operation table as soon as the characteristic granules were perceived in the pus. Iodide of potassium was used in the treatment of all three and was probably of service in the third case. For the notes of these cases we are indebted to Mr. Thomas Carwardine, senior resident officer.

CASE 1. (Under the care of Mr. Greig Smith.)—A man, aged twenty-three years, was out in a strong wind on March 20th, 1896. He had some chaff loose in the pocket from which he took his handkerchief to wipe his nose, in doing which some dozen small pieces of chaff blew into his mouth. He managed to get rid of all but one piece, which appeared to be forced into the floor of his mouth by the tongue in the endeavour to remove it. About a fortnight afterwards he came to the Infirmary, but nothing definite could be found. Next day his right lower first molar began to ache and was removed. Two weeks later a swelling appeared beneath the lower jaw on the right side and soon spread across to the left side. He was admitted as an in-patient on June 12th. On admission he presented the signs of a sub-acute sub-maxillary cellulitis extending across the crop of the neck. The swelling was slightly red, but very tender and brawny. The floor of the mouth was hard and raised and pushed the tongue upwards and backwards. There was some obstruction to laryngeal respiration and preparations were made for a possible immediate laryngotomy or tracheotomy. With fomentations the condition of the mouth improved, but an abscess formed in the middle line of the neck. This was opened on the 14th, but on searching the pus no granules could be seen. On July 14th another abscess was opened on the right side containing about half a drachm of pus with some suspicious granules, which, on microscopical examination, proved to be masses of the ray fungus. The patient was put on ten grains of iodide of potassium thrice daily, and several small abscesses which have from time to time appeared have been similarly treated. The disease now seems to have spent itself and the patient is in perfect health.

CASE 2. (Under the care of Mr. Harsant.)—A healthy-looking countryman, aged sixty-five years, came into the infirmary on Nov. 9th, 1896. About two months previously he was preparing some thatch from the straw of Italian wheat when he experienced a pricking sensation in the throat due to the lodgement of one of the fine "spears" of the wheat. The sensation remained for about two days and then he felt nothing more for a fortnight. Then a lump appeared under the left side of the jaw and it continued to increase up to the time of his admission. When admitted a firm, smooth mass was present in the left sub-maxillary region, but slightly tender, fairly fixed, apparently infiltrating into the surrounding tissues, and rather adherent to the skin. On the left anterior pillar of the fauces was a small ulcer with scarcely any induration, but marked congestion around it. Iodide of potassium was given, but discontinued on account of iodism. On Nov. 18th the mass below the jaw was opened and scraped, some puriform material escaping. Microscopical examination confirmed the diagnosis of actinomycosis. The patient was discharged on Dec. 7th, the wound being practically healed as well as the ulcer on the fauces.

CASE 3. (Under the care of Mr. Paul Bush.)—The patient was a man, aged thirty-nine years, who had been for some time in the medical ward with a gradually increasing swelling of the chest the nature of which could not be determined. It was thought possible that it might be a residual empyema, a sarcoma, a gumma, or necrosis of rib. There was a large, rounded, semi-fluctuating, boggy, and tender swelling extending from the left clavicle to the upper border of the fourth rib and from the sternum to the left axilla. The patient was operated upon on May 21st. A little pus came away from the incision and granules were recognised at once and the diagnosis cleared up. Subsequent microscopical examination proved confirmatory. The surrounding tissues and pectoralis major were much involved and indurated. A considerable portion of the pectoralis major was cut away, a counter opening made in the axilla, and the area thoroughly scraped. No communication with the pleural cavity could be discovered. On June 9th the operation was repeated and iodide of potassium was now administered. On the 26th a fluctuating swelling appeared over the left supra-scapular fossa and the iodide of potassium was increased to twenty grains three times a day. From this time the dose was augmented until the patient took fifty grains thrice daily. Subsequently one or two collections appeared in the upper part of the back and were opened and scraped. From time to time a little blood-stained expectoration occurred, granules being absent, but apart from this there was no indication to show that the lung itself was involved.

Remarks by Mr. CARWARDINE.—Notwithstanding the large amount of iodide the patient in Case 3 had taken he has become much stouter than before and weighs more than he ever did in his life. The condition in front of the chest quieted down, excepting one or two very small unhealed places. At the back of the chest, however, there is a soft superficial fluctuating mass. There is no distinct evidence that the pleura or lung is involved, and there are reasonable hopes that the affection will in time be cured. Very careful inquiries have been made to find out the cause in this case, but without result. He worked for a large firm, and full inquiries were made of the firm, but to no purpose. He was, he said, fond of putting spills of shavings of wood into his mouth; but the most interesting fact is the following, which was elicited without leading questions and checked by cross-examination. He states that he has much more than most people a predilection for sucking hay and straw. The habit with him is so irresistible that if he saw a hay-cart on the other side of the road he could not resist the temptation to cross in order to get a piece to suck. He seems, indeed, to have the imperative idea that he must suck straw whenever possible. In view of the causation of actinomycosis this propensity seems worth mentioning as having some bearings on the case. Grouping the cases together a few points are worthy of special notice. For instance, the periods of incubation between the inoculation and the appearance of marked swellings seem to have been considerable. Although the appearances of each were quite characteristic there was some slight diversity in the microscopical characters, for it was noticed in Case 2 that the amount of mycelial threads was very great indeed as compared with the number of the true ray elements. Some parts of the specimen appeared to present a field full of such threads without any complete actinomycetes—threads quite distinct from isolated club-shaped processes. The effect of iodide of potassium can only be estimated in Case 3, and as this case has greatly improved, although it appeared almost hopeless from a surgical point of view, some considerable benefit may have been derived from it. The rapid disappearance of the granules from the discharge under iodide of potassium, as has been recorded in similar cases, was not, however, observed in this case. An opportunity of testing this may come later. The possibilities of diagnosis and the favourable termination in these cases will not be lost sight of. I have to thank the respective surgeons for their kind permission to record the above cases.

SWANSEA HOSPITAL.

A CASE OF DISLOCATION OF THE OUTER END OF THE CLAVICLE UNDER THE ACROMION PROCESS.

(Under the care of Mr. N. FOX EDWARDS, House Surgeon.)

THIS dislocation is perhaps more correctly described as a dislocation of the scapula upwards. It is a very rare displacement, the usual dislocation of the acromial end of the clavicle being upwards on the acromion. In order to produce it the force must be applied to the upper surface of

Hosted by Google

the clavicle; and the conoid, trapezoid, and acromio-clavicular ligaments are all ruptured. The diagnosis of the condition is easily made.

The patient, a football player, was brought to the casualty department on Jan. 31st, 1896. He complained of having injured his right shoulder by falling heavily. He was an unusually well-developed man. On examining the right shoulder a projection in the region of the acromio-clavicular articulation was found. On tracing the clavicle outwards it gradually disappeared under the projection. On examining the prominence it was found to be directly continuous with the spine of the scapula. On pressing the shoulder back the deformity disappeared, this being accompanied by no crepitus, but by a certain amount of pain. The treatment adopted was to apply strapping in a manner similar to Sayre's method of treatment for fractured clavicle—more with the intention of forcing the shoulder back than of raising it. A gutta-percha splint was then moulded over the shoulder and the whole fixed with a broad bandage, the bandage passing over the top of the shoulder from behind forwards as near as possible to the neck.

Remarks by Mr. EDWARDS.—The question of cutting down on the two disarticulated bones and wiring them I considered, but as a few weeks' holiday would not leave the patient financially poorer, thanks to insurance, I determined to try the above method in preference to the additional, although slight, risk of a cutting operation. The patient then passed out of my hands, but I again had an opportunity of examining him some months afterwards, and found he had kept the appliance on for six weeks with a most successful result. There was no difference in the shoulders to be discovered.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Perforating Typhoid Ulcer treated by Operation and Suture; Recovery.—Jaundice and Perforation of the Gall-bladder in Typhoid Fever.

A MEETING of this society was held on Jan. 26th, the President, Dr. HOWSHIP DICKINSON, being in the chair.

Dr. LAUDER BRUNTON and Mr. BOWLBY reported a case of Perforating Typhoid Ulcer treated by operation and suture and resulting in recovery. The patient, a man aged thirty-seven years, was admitted into St. Bartholomew's Hospital on Oct. 3rd, 1895, at about the end of the second week of typhoid fever. The case was a severe one and was complicated by hæmorrhage from the bowel soon after admission and by a relapse on Oct. 30th. The relapse lasted nearly a fortnight, and was followed by a slow convalescence till Dec. 14th, when there was a sudden attack of severe abdominal pain, followed after some hours by abdominal distension and symptoms of obstruction, but without nausea or vomiting. There was no evidence of free gas in the peritoneal cavity and the distension was chiefly in the lower half of the abdomen. Laparotomy was performed about eighteen hours from the commencement of the pain. The patient was placed under the influence of chloroform and the abdomen was opened in the middle line below the umbilicus. The upper part of the peritoneal cavity was free from gas or fæcal matter, but the great omentum was adherent in the pelvis, and as soon as it was separated it was found that the whole of the intestines beneath it were matted together. On freeing the uppermost coils about half a pint of fluid was let loose. It was dirty-yellow in colour and evidently consisted of some intestinal contents mingled with peritoneal exudation. On passing the hand into the cavity amongst the intestines from which this fluid had escaped a very indurated coil of bowel could be felt, which after a little trouble was separated from its adhesions and drawn out of the abdomen. It was then seen that the gut had been perforated by a small ulcer about as large as a pea, situated opposite to the attachment of the mesentery. This ulcer was evidently in the centre of an inflamed Peyer's patch, for an area of induration corresponding in size to such a patch could be felt in the wall of the bowel. The whole coil of intestines was covered with old and recent lymph, and was thickened and œdematous. This lymph was removed as thoroughly as possible and the whole bowel very carefully washed. Ten silk sutures were then passed after Lembert's method transversely to the long axis of the bowel, which was clamped by the fingers of the assistants. The sutures furthest from the ulcer were passed clear of the indurated Peyer's patch, so that the line of suture was about one and a half inches in length. Flatus and fluid matter were then allowed to enter the sutured coil of gut, and it was found that there was no leakage and that the lumen was free. The abdomen was finally irrigated with hot water until all foreign matter seemed to be quite removed, and, a drainage-tube having been passed into the pelvis, the wound was sutured. The operation lasted about forty minutes and the patient was not at all collapsed at its conclusion. Some difficulty in passing sutures was caused by the induration of the inflamed Peyer's patch and the friability of the intestinal wall. Recovery was uninterrupted, the temperature remaining normal throughout. The tube was removed in forty-eight hours and for four days no food was given by the mouth except water in teaspoonful doses. The bowels acted on the fifth day after the use of an enema, and for the next month the patient was very carefully dieted. He left the hospital on Feb. 21st in good health and returned to his work in April. When seen on April 15th he had regained his normal weight and the bowels acted regularly. For several weeks after operation he had a slight "dragging pain" in the abdomen and a feeling of tightness, but this gradually passed away. It was pointed out that the case was one unusually well adapted for operative treatment and could not be compared with those cases where perforation occurred during the height of the fever and in a patient greatly prostrated by the disease. It was probable that the perforation in the bowel had really existed for some time and had been temporarily but insecurely closed by adhesions. These had gradually yielded when a fuller diet was allowed, and had permitted an escape of the contents of the intestine. It would appear that the case described was the third recorded case of the kind submitted to operation in this country and the first to arrive at a satisfactory termination.

Dr. HERRINGHAM and Mr. BOWLBY reported a case of Typhoid Fever in which symptoms of Perforation occurred during Convalescence. Laparotomy was performed, but no lesion found. Recovery followed. Though perforation in typhoid fever was allowed to be almost invariably fatal, cases had from time to time been recorded in which symptoms usually held to indicate this event had yet been followed by recovery. Whether in these cases the bowel had actually been perforated must always remain doubtful, and it had been pointed out by Fitz that there were no trustworthy signs which were pathognomonic of perforation, and that the occurrence of even a local peritonitis alone would be quite sufficient to explain the condition. That the same symptoms might occur even when there was no peritonitis at all was shown by the following case. A girl, aged thirteen years, who was passing through an attack of typhoid fever had a subnormal temperature on and after the twenty-second day. On the twenty-eighth day symptoms appeared like those of perforation—namely, acute pain, frequent vomiting, and small pulse, together with rigidity and tenderness of the abdomen. These symptoms came on suddenly. The bowels had been open the day before. An oil enema was administered, but neither this nor the administration of morphia gave any relief. After three and a half hours it was considered advisable to perform laparotomy. No abnormal condition was found except that the colon contained scybala. Recovery was uneventful. The condition, although giving rise to alarming symptoms, was evidently due to constipation. The patient was in good condition, or the operation would not have been attempted.

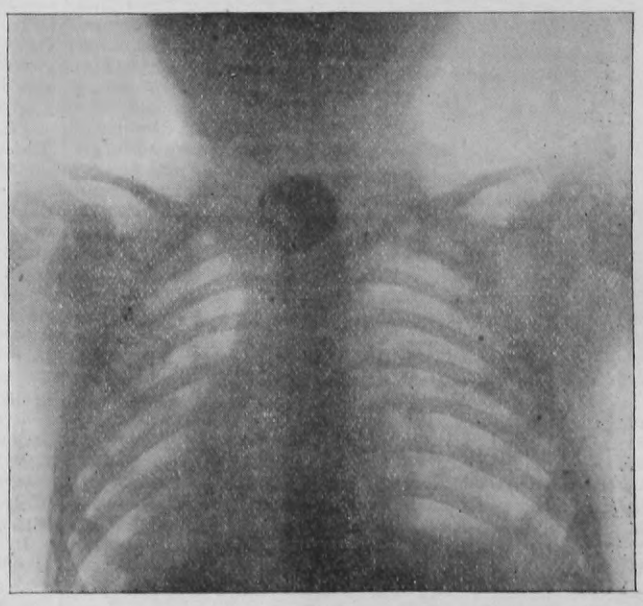
Dr. LAUDER BRUNTON supplemented the report of this case by mentioning one which he had seen recently, in which a man who had been going about his work during the early stage of typhoid fever was admitted in a very weak condition at about the end of the third week. Hæmorrhage occurred and sloughs were passed. A week after admission symptoms of perforation occurred, but the patient was too weak and the pyrexia too great for an operation to be advised. Post mortem a pin-hole perforation was found and very extensive ulceration throughout the large intestine.

Dr. NORMAN MOORE congratulated Dr. Brunton and Mr. Bowlby on the encouraging result in their case. Physicians often met with cases in which they would be glad of surgical assistance. There were several circumstances which would aid the surgeon. The locality of the lesion was known within

Hosted by Google

limits. Out of twenty-one consecutive cases at St. Bartholomew's Hospital the lesion was within two feet of the ileo-cæcal valve in half the cases and within three feet in three-quarters. He thought the usual date for perforation was put too early in many books. He had found localised peritonitis over the site of the ulcer of frequent occurrence in cases without perforation, and hence when perforation occurred the resulting peritonitis would be less general than in cases of gastric ulcer. Dr. Herringham's case had an important bearing on the cases which were supposed to have perforated and recovered spontaneously. He himself had never seen on the post-mortem table any cicatrix such as would result from the healing of a perforation.—Dr. GOODALL could not agree with Dr. Norman Moore that localised peritonitis was common in typhoid fever. He had only met with it in one out of many necropsies. He considered that the date of the disease was not an accurate index of the stage of the intestinal lesion. He thought the symptoms in some of the reported cases which recovered spontaneously might be due to a suppurating mesenteric gland.—Dr. SIDNEY PHILLIPS remarked that in the case where there was actual perforation the symptoms were indefinite, while in the simulated case they were apparently typical. He had frequently seen cases in which sudden symptoms of perforation had quickly subsided, but he doubted if any true cases of perforation had recovered spontaneously. He thought an operation should be performed as soon as it was clear that a perforation had really occurred. He had not seen lymph on the intestines as described by Dr. Norman Moore. He thought leakage was minimised in the cases where there was much distension. Where the intestines had lost their tone, and the abdomen had a doughy feel, and symptoms were masked, extravasation occurred more readily.—Mr. WALLIS thought that much harm was done by waiting too long and that there was too great reluctance on the part of physicians to recommend surgical interference in abdominal cases.—Mr. BOWLBY, in reply, said that in this case he was pressed urgently by Dr. Lauder Brunton to operate. He thought that Dr. Goodall's theory of inflammation of mesenteric glands was a very reasonable explanation of many cases. Although both his cases had recovered he thought a caution was necessary. Both of them were convalescent and in good condition; but if there were fever or much prostration the operation was by no means lightly to be undertaken.

Dr. FRANCIS HAWKINS read a paper on Jaundice and on Perforation of the Gall-bladder in Typhoid Fever. He remarked that cases of jaundice with typhoid fever were very rare. He had recently observed a case in a female, aged eighteen years, who while suffering from typhoid fever complained of pain in the abdomen and back, the abdomen being tumid and showing pink spots; the liver was slightly enlarged and the bowels were irritable; the pulse was 96 and regular; the respiration was 44 with râles, and the temperature was 104° F.; the urine was free from albumin and of specific gravity 1030. As regarded the progress of the case, for the first five days there was constant pain in the back and legs; food was rejected, the bowels being frequently opened; at night there was delirium. There was formation of fresh spots. The temperature varied from 102° to 104 4°, and the respiration was 36. On the next day pain (severe) occurred in the right half of the epigastric region and over the right lower axillary and hypochondriac regions; the respiration was 40 per minute, with evidence of dry pleurisy over the right base and the axillary and lower mammary regions. This vomiting was constant, the temperature being 105 8°. On the following day the conjunctivæ and the skin of the upper part of the body were jaundiced, bile was found in the urine, and the stools were frothy and white. The jaundice increased, the pain over the above-named regions became more severe and extended round the umbilicus, and the region of the gall-bladder was exquisitely tender. Bile appeared in the urine; both urine and fæces were passed unconsciously. The respiration was 50 per minute, the breathing being mainly abdominal, and dry pleurisy developed on the left side as well as on the right. After this the pain over the epigastric region lessened, ultimately disappearing. Bile was vomited and jaundice persisted till death, having lasted for three weeks. Once, and for one day, with the exception of the conjunctivæ being yellow, it quite disappeared. Ten days before death dyspnœa was extreme, the face was cyanosed, the soft parts were drawn in, and the respiration was 56 per minute (the breathing was abdominal), varying from 60 to 80. The patient died from the pulmonary complications. The stools at the first onset of the jaundice were white and frothy and later were more coloured (on three or four occasions containing bile), and were passed unconsciously. Hæmorrhage from the bowels was more or less constant for nine days, many of the stools being pure blood. There was delirium, this being constant at night and frequent by day. There were bullæ on the left leg, with dark-reddish margins; many pink petechiæ were present on both legs, which subsequently disappeared, as did the bullæ, leaving scars. A swelling (of the size of a Tangerine orange) on the left hip also disappeared. At the necropsy the body was found to be greatly emaciated. Both lungs were markedly pale and collapsed, with consolidation at the base of the right and at the apex of the lower lobe of the left. Ten ounces of turbid fluid was found in the right pleural cavity. The cardiac walls were flabby, the right ventricle was dilated, the valves being normal. The gall-bladder was adherent to the peritoneum, and around the adhesion there was a small area of peritonitis; the anterior wall of the gall-bladder showed a perforation. The contents of the gall-bladder were purulent; the walls were thin, especially on the posterior surface, where there was also almost perforation. There was a gall-stone lying free in the gall-bladder. The liver was uniformly enlarged, showing cloudy swelling, but exuding no bile. There was typical ulceration of the intestine.—Mr. MARMADUKE SHEILD said that he had operated successfully in a case in which perforation of the gall-bladder during typhoid fever gave rise to general peritonitis. It was published in full detail in THE LANCET of March 2nd, 1895.—Dr. JOHN HARLEY said that jaundice was rare in typhoid fever, except as an early and transient symptom. He had seen one case in which perforation of the gall-bladder occurred in a patient convalescent from typhoid fever. Adhesions prevented extravasation, but an epigastric swelling formed, and on incision many small calculi and some colourless bile were evacuated. From the absence of bile pigment in the calculi he thought the cholesterin had been deposited during the attack of fever.



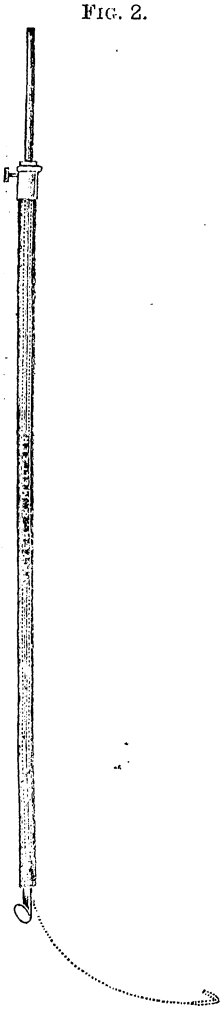
CLINICAL SOCIETY OF LONDON.

Clinical Evening.—Exhibition of Cases.

A MEETING of this society was held on Jan. 22nd, the President, Dr. BUZZARD, being in the chair.

Mr. A. A. BOWLBY, for Mr. HOWARD MARSH, showed

FIG 1.



Skiagram showing coin in œsophagus.

Hosted by Google

two cases of Coins Impacted in the Œsophagus. The first patient was a boy, aged three and a half years, who had swallowed a halfpenny. He was under observation for five weeks, but had exhibited no symptoms beyond occasional sickness. A skiagram[1] revealed (Fig. 1) the coin in the œsophagus at the level of the second dorsal vertebra. The coin could not be felt with the finger, and an attempt to remove it with a coin-catcher failed and no better success followed an attempt with forceps. Ultimately its removal was readily effected by the aid of a coin-catcher concealed within a gum-elastic catheter (as suggested by Mr. A. A. Bowlby) until the instrument had passed the coin (Fig. 2.) The second patient was a boy, aged three years, who was also said to have swallowed a similar coin. No pain or other urgent symptoms were manifested and the presence of the halfpenny could not be ascertained—it could not be reached by the finger—till a skiagraph was taken. Removal was easily effected with the instrument described above. — Mr. CLEMENT LUCAS recalled the case of a child, aged two and a half years, who had swallowed a halfpenny, and this was followed by some difficulty in swallowing. He was unable to remove the coin with the coin-catcher, and he pointed out that as coins usually lie transversely in the œsophagus forceps were useless unless they opened antero-posteriorly.

FIG. 2.

The coin-catcher in the catheter showing it extended and also pulled up against the catheter for the purpose of passing the obstruction.

Mr. H. G. CROLY (Dublin) showed a case of Ligature of the Second Part of the Sub-clavian Artery for Aneurysm in a man, aged thirty years, who was stabbed with a pair of tailor's scissors in 1893. Free hæmorrhage followed, which was checked without much difficulty, but when he began to use his arm again a tumour formed behind the clavicle. There was some loss of power in the arm and wasting owing to the pressure of the tumour on the brachial plexus. The usual methods of treatment were tried without success, and two years after the injury he ligatured the sub-clavian artery in its second part, tying the vessel with ligatures made of gold-beaters' skin, as suggested by Mr. Ballance, using the stay knot also suggested by him. The radial pulse returned in four weeks, and the paralysis had now almost completely passed off.—Mr. BALLANCE said he had seen the patient before he was operated upon and the tumour was certainly a very large one, extending both above and below the corresponding clavicle.

Mr. G. STOKER brought forward two patients, one of them suffering from Chronic Ulceration of the Leg and the other from the results of an injury, both treated by Oxygen. The first patient sustained a severe injury to his leg on April 10th, but healing was delayed, and on July 17th the ulcer was treated with 50 per cent. of oxygen, and the pain and fœtor speedily disappeared, and he was discharged cured on Sept. 4th. Bacteriological examination of the ulcer revealed the presence of the staphylococcus albus and aureus, together with streptococci. The other patient came under observation on Oct. 23rd. His leg had been painful for twenty years and had ulcerated ten years before. The leg presented a deeply excavated ulcer, with irregular, rough, thickened margins; there was considerable discharge, which was very offensive, and the ulcer was most painful. He was treated in the same way, and in less than four weeks the ulcer on the inner side of the leg had completely healed, and the other was in a fair way to recovery. Bacteriological examination showed the rod bacterium and the bacillus subtilis. Later he found only staphylococci and streptococci.—In reply to Mr. SPENCER WATSON Mr. STOKER stated that he had tried hydroxyl in place of oxygen, but found it more irritating and less convenient.

Dr. SIDNEY PHILLIPS showed a female, aged thirty-one years, with complete paralysis of the left fifth nerve. The following symptoms were present: anæsthesia and analgesia of the left side of the face and of the mucous membrane of the inner side of the cheek and that covering the soft and hard palate; the teeth on the left side were insensitive to pressure and several had become loose; loss of sensation over the left side of the tongue, and loss of sense of taste in the anterior part of the tongue and also over the posterior third, where strychnine, sugar, and salt were not recognised by the patient; anosmia, with a sanious, ichorous discharge from the left nostril and frequent epistaxis; conjunctival injection with a large area of cloudiness on the surface of the cornea; unless the eye was kept protected by a watch-glass small ulcerations of the corneal surface occurred, and even with this protection there was a tendency to growth of vessels over the cornea, which was checked by atropine locally; sight on the left side was defective, but there was no optic neuritis; the disc had latterly, however, become unduly white. The motor part of the fifth nerve had been entirely paralysed, but during the last few days some contraction of the masseter and temporal muscles could be felt; the jaw at one time deviated much more than at present towards the paralysed side when the mouth was opened. The illness commenced with sudden acute pain in the forehead and behind the eyes, with nausea and shivering, in August, 1896. At one time there had also been staggering gait and a little numbness of the left hand. These symptoms had all passed away under treatment by iodide of potassium, leaving the fifth nerve paralysed. The signs of improvement in this respect had only come on during the last few days under treatment by mercury. The eye had been injured about five years before by a fork, but not sufficiently to require medical advice, and the symptoms were probably the result of syphilis, seeing that the three first children of her marriage were born prematurely and dead and that specific treatment had influenced the symptoms. Dr. Phillips thought the lesion was in, or around, the Gasserian ganglion.—The PRESIDENT agreed that the affection was probably specific and that the improvement under treatment was against the probability of a nuclear origin. The Gasserian ganglion was probably the seat of the lesion.

Mr. C. W. MANSELL MOULLIN showed a case of Hæmo-pericardium. The patient, aged twenty years, received a severe blow over the sternum while playing at football on March 28th, 1896. He was able to go on playing for twenty minutes, but on arriving at his home he suddenly collapsed. At 9 P.M. on that day his pulse was about 60, but the heart was apparently beating about twice as quickly. There was no increase of cardiac dulness, but some difficulty in swallowing existed and there was great pain on the left side. The breath sounds were very loud all over that side and the temperature was 96° F. No urine was excreted for twenty-four hours after the injury. Thirty-six hours after the accident he was seized with a violent cough, accompanied by profuse expectoration, and he perspired profusely. The pulse was 140, the breathing 22 per minute, and his temperature 100·4°. The area of cardiac dulness gradually increased until it spread to the right of the sternum. On April 22nd, three weeks after the accident, he was seized with violent dyspnœa, and then the whole of the left side of the chest was found to be distended and motionless. The heart sounds could only be heard in the right second interspace. Mr. Mansell Moullin then made an incision through the fifth left space and exposed the pericardium, which was incised and a drainage-tube was inserted. Altogether some six pints of blood escaped through the tube within the first three hours and this clotted firmly in the basin. The dyspnœa at once disappeared, the tube was removed on the following day, and the patient was able to sit up in a week. The left lung remained collapsed for a long time, but now, ten months after the injury, he had returned to work and was again playing football. Mr. Mansell Moullin believed that a branch of the coronary artery must have been the source of the hæmorrhage.

Dr. H. G. TURNER showed a case of Multiple Nodules in a man who was suffering from renal disease and whom he had had under his observation for about twelve months, during which time he had developed more or less symmetrical nodules, at

[1] Taken by Messrs. Allen and Hanburys, Wigmore-street.

Hosted by Google

first over the upper half of the body, but later elsewhere. Their distribution was not that of the rheumatic nodules, with which they were familiar. Some of them appeared to be connected with bone and were fixed, while others were freely moveable under the skin. For the present he preferred to describe the case as one of multiple fibromata of uncertain origin.

Dr. TURNEY also showed a man, aged sixty-five years, who had had Ptosis on the left side and complete Ophthalmoplegia for the last twenty years. During the last ten years there had been atrophy of the muscles round the shoulder. None of the muscles supplied by the fifth or lower cranial nerves were affected nor were the neck muscles. The lesion was evidently a nuclear one, and it was difficult to account for the escape of these intervening muscles.

Mr. R. CLEMENT LUCAS exhibited a patient suffering from Elephantiasis on whom he had performed the operation of ligaturing the femoral artery. A man, aged forty-five years, a native of Leicester, who had never been abroad, suffered twelve years previously from inflammation and thrombosis of the left internal saphenous vein, when his leg and foot swelled up, but gradually subsided again. Two years ago he cut a corn on the little toe of that limb, which he neglected. The toe sloughed away and he was in St. Thomas's Hospital for eight weeks, pieces of bone coming away at intervals since, but it was now healed. At this time the leg swelled again and had gradually increased in girth. The right leg and foot had also lately commenced to increase in size. The left leg and foot were œdematous and the cuticle about the heel greatly hypertrophied at the time of admission. Mr. Lucas ligatured the superficial femoral artery of the left leg on Dec. 18th, 1896, with a sterilised silk ligature, sterilised pads being used as dressing. Primary union without any rise of temperature followed, and three weeks afterwards the limb measured two inches smaller around the calf than before the operation. Good circulation followed in the foot.—Mr. F. C. WALLIS quoted a similar case in which no improvement followed ligature of the femoral artery. He asked if rest in bed accounted for the diminution in the size of the limb.

Dr. COLMAN showed a case of General Muscular Weakness following Infantile Paralysis. A boy, aged four and a half years, had an attack of infantile paralysis affecting the left latissimus dorsi, deltoid, triceps, and intrinsic muscles of the hand when aged eight months. During the last twelve months the opposite arm and both legs had become weak, some of the muscles being much wasted. All of them, except those originally paralysed, re-acted readily to a moderate faradaic or galvanic stimulus. The knee-jerks were exaggerated and there was marked pes cavus on each side. The condition was possibly due to slow extension of the poliomyelitis with some sclerosis of the white columns, although the electrical reactions hardly favoured this view.

MEDICAL SOCIETY OF LONDON.

Operation for Vesico-Vaginal Fistula.—Re-section of Sigmoid Flexure.—Laparotomy for Strangulation by a Band twice in the Same Patient.

A MEETING of this society was held on Jan. 25th, the President, Mr. REGINALD HARRISON, being in the chair.

Mr. STANMORE BISHOP described an operative method he had used with success for closing a Vesico-vaginal Fistula. He reviewed in detail the various methods that had been employed during the last two centuries with very indifferent success for the purpose of relieving this distressing condition. His own method of operating was as follows. The patient having been prepared, a circular incision was made through the vaginal mucous membrane, which was then reflected. Four stitches were then passed through the flap but not tied. Specially devised curved forceps were introduced per urethram and through the orifice to catch the sutures, the threads of which were withdrawn by the forceps and allowed to hang out of the urethra. By gentle traction on these a kind of frill was everted into the bladder. Before any firm traction was made a circular purse-string suture was passed from the vagina through the connective tissue only of the flap. This was secured to close the orifice and sometimes a second suture was desirable. The loose sutures originally introduced were easily withdrawn through the urethra. In cases where an extensive raw surface was left on the vaginal side it might be advisable to apply a Thiersch graft from some hairless part of the body. The vagina was stuffed for a few days after the operation. He claimed as advantages for the method that there was no tension of the uniting surfaces, the mucous floor of the bladder was re-formed, and the capacity of the bladder was not interfered with. The sutures were buried and did not project into the lumen. The thickened cicatricial edge of the fistula supported the wound like a splint.—The PRESIDENT considered he method very ingenious, but thought there might be some risk of a calculus forming at the site. In two cases he had been obliged to re-open a bladder some time after supra-pubic cystotomy, in consequence of phosphatic deposition occurring along the line of his original incision.

Mr. HERBERT ALLINGHAM showed a patient, sixty-four years of age, on whom he had performed resection of the Sigmoid Flexure six months before for a Malignant Stricture. There was a history of hæmorrhage, pain, and tenesmus for six months before operation, with alternating diarrhœa and constipation. Nothing could be felt under an anæsthetic, either per rectum or through the abdominal walls. The symptoms subsided for a time under medical treatment with rest in bed, but returned with some severity, and laparotomy was performed, and the sigmoid flexure was found to be partially occluded by a growth, which proved to be a columnar-celled carcinoma. The gut was ligatured by drainage-tubes above and below, and the growth and part of the mesentery rapidly removed in the way advised by Mr. Mayo Robson. The ends of the intestine were cleansed and approximated over one of Mr. Allingham's bobbins of decalcified bone. There was some discomfort a day or two after the operation, which was at once relieved by releasing flatus through a rectal tube. The bowels acted a week after operation. During the third week there was a little escape of pus with a fæcal odour through the wound, but this soon ceased. Although the motions were watched no signs of the bobbin were observed, and it was probably absorbed.—Mr. F. C. WALLIS asked for details as to the method of suture.—Mr. J. H. MORGAN referred to the difficulty often experienced in uniting the ends of the bowel in cases where there were hypertrophy and dilatation of the bowel above the stricture and contraction below, and asked how Mr. Allingham would deal with such cases.—Mr. ALLINGHAM, in reply, said that he would completely close each end of the intestine by careful suturing and obtain anastomosis by lateral approximation. He had fully described the details of suturing the intestine over his bobbin in Vol. XVI. of the Society's Transactions.

Mr. G. R. TURNER related a case in which Laparotomy had to be performed on two occasions in the same patient for Strangulation under a Band. The woman, in July, 1895, was seized with sudden pain six days before the first operation and symptoms of complete intestinal obstruction quickly followed. On opening the abdomen a volvulus of the small intestine (probably secondary), with extreme torsion of the mesentery, was found and easily relieved. A loop of about six inches of small intestine was found tightly strangulated under a band in the right iliac fossa. It was very deeply congested and there was some recent lymph on the surface. The band was divided. The woman rapidly recovered in spite of the long duration of symptoms. Six months later she was re-admitted to St. George's Hospital, having been seized with sudden pain and vomiting the day before. The incision was re-opened, but owing to the small intestine being adherent it was wounded. The opening was at once closed by Lembert's suture. The small intestine was found to be strangulated by a band situated this time in the right hypochondrium and evidently inflammatory in character, no doubt the result of some peritonitis during the previous attack.—Mr. WALLIS mentioned a case published by Mr. Harrison Cripps in which adherent intestine was wounded in re-opening an incision in the middle line.—Mr. SWINFORD EDWARDS thought it best to avoid the site of a former incision in re-opening the abdomen.

EPIDEMIOLOGICAL SOCIETY.

Age Incidence in Relation with Cycles of Disease Prevalence.

A MEETING of this society was held on Jan. 15th, Professor J. LANE NOTTER, President, being in the chair.

Dr. W. H. HAMER read a paper on Age Incidence in Relation with Cycles of Disease Prevalence, in opening which he

Hosted by Google

referred to the several hypotheses that had already been advanced as explanations of the tendency of epidemic diseases, such as small-pox, scarlet fever, measles, and whooping-cough, to variations or waves of prevalence and of intensity, which, however, did not coincide. There was the theory of variations in the intensity of the poison, of the mere accumulation in the course of years of susceptible persons of the ages most liable, and Dr. A. Ransome's modification of the latter, that a certain density of susceptible population or proximity of the individuals was a necessary condition of widespread infection. Dr. Ransome had also pointed to the co-existence with the great epidemic waves, recurring at longer intervals, of shorter cycles of lesser range "like ripples on the billow." The late Mr. Netten Radcliffe had called attention to extraneous causes of varying severity of epidemics, and Dr. Whitelegge had insisted on a progressive intensification and attenuation of the virus as the cause of the greater wave cycles, movements of the population and accidents accounting for the smaller, the former being most marked in the less stable diseases, in which the quality rather than the quantity of the virus determined the prevalence of the disease. In each great epidemic there were, too, a progressive rise and fall of intensity or virulence not observed in the lesser seasonal or accidental outbreaks; but no such regular variation was to be observed in small-pox—a disease of constant type and character. Hirsch, indeed, denied that there were any factors besides the virus and a susceptible, because unvaccinated, population, though he recognised others in scarlet fever. It was Mr. Shirley Murphy who first demonstrated in the case of diphtheria and scarlet fever the influence of school attendance on their incidence on certain age periods. Dr. Hamer then exhibited a number of lantern views of diagrams showing graphically the incidence in successive quarter-years of measles, scarlet fever, and small-pox in each year of age up to five years, from five years to ten years, and ten and upwards calculated on a standard of 100 at all ages. These [which will, at the unanimous desire of the members, be reproduced in the Transactions] showed very clearly the greater and long period waves, the lesser intermediate fluctuations, the inverse ratio often subsisting between the death-rate and the case-mortality or the prevalence and the intensity of the disease, and between the general incidence and that on the age of greatest susceptibility. Some of the diagrams were calculated on different bases and some were inverted to convert inverse into direct ratios. These phenomena, which demanded leisurely investigation, were best seen in scarlet fever and, except as regards the minor curves, in small-pox, but were little marked in measles and whooping-cough. Dr. Ransome's view that the longer intervals between the great epidemic waves in Sweden, as shown by Dr. Berg's tables, were due to the sparseness of the population, was fully borne out by a comparison of those of London and the more densely peopled districts with those of the most purely rural character. In the case of small-pox the incidence of the disease in early and middle life respectively in the "fifties" and the "seventies" was distinctly influenced by the extension, and in the "nineties" again by the neglect, of infant vaccination. There had not, however, been notification of scarlet fever long enough to permit of positive conclusions, and there was little probability of that of measles and whooping-cough being generally adopted.

Dr. WILLOUGHBY felt that such a paper as Dr. Hamer's could not be adequately criticised except in one's study, but he would have preferred to see the age incidence stated on the number living at each age, as Dr. Hamer hoped to do at a future time. He also questioned the utility of such "actuarial" discussions of small-pox; the prevalence and age incidence of which were dominated by the extent of vaccination and re-vaccination, and the great epidemic wave of 1871-2 was brought about directly by French prisoners in Germany and refugees elsewhere.

Mr. SHIRLEY MURPHY held that the prevalence of small-pox when introduced into a locality depended on the aggregation of susceptible individuals. In autumn, when scarlet fever was most prevalent, its incidence was greatest on ages of from five to ten years and the case-mortality was lowest.

Dr. WHITELEGGE maintained that the greatest incidence of scarlet fever in early life and the highest case-mortality occurred in the intervals of lesser prevalence, indicating periodic variations in the intensity of the virus. The greater prevalence in autumn did not involve a high case-mortality because it took in ages of less fatality. As to Dr. Longstaff's suggestion of a relation between the rainfall and the prevalence of scarlet fever, he thought that drought might aggravate and wet might minimise a rise predetermined by other factors, and conversely of a fall, but could not be deemed a cause of such rise or fall.

Dr. HAMER briefly replied.

HARVEIAN SOCIETY OF LONDON.

The President's Address.—Election of Officers.—Conversazione.

THE annual meeting of this society was held on Jan. 21st at the Stafford Rooms, Titchborne-street, Edgware-road, Dr. WILLIAM HILL, one of the Vice-Presidents, being in the chair.

After reading the report of the council, which showed that the society was flourishing both in point of numbers and financially, Dr. CAGNEY, the senior secretary, read the President's address, the President, Mr. J. KNOWSLEY THORNTON, being absent owing to serious illness in his family. Mr. Knowsley Thornton dealt with certain lessons derived from his experience during twenty years of practice as a consulting surgeon. Speaking of his early enthusiasm for the microscope he admitted that it failed to satisfy all his expectations, and that its appearances were never to be depended upon alone when clinical observation was available. Speaking on the subject of abdominal surgery he dwelt upon the need that there was in view of the ease or immediate security attending operative procedure for care and forethought of ultimate results. Removal of the appendages he thought was too often needlessly practised. Removal of the vermiform appendix appeared to be becoming a routine procedure: he deprecated this, and dwelt briefly upon the dangers and disadvantages incident to it. In conclusion he paid a generous tribute to the life and labours of Lord Lister.

The following officers for the year 1897 were then reported by the scrutineers to be elected without opposition. President: Dr. R. H. Milson. Vice-Presidents: Mr. Argles, Dr. Boxall, Mr. Juler, and Dr. Lamb. Treasurer: Mr. Edmund Roughton. Honorary secretaries: Dr. F. W. Cock and Mr. Jackson Clarke. Council: Mr. R. S. Armstrong, Mr. E. Bartlett, Mr. Peyton Beale, Dr. Cagney, Dr. Gee, Dr. Gow, Mr. J. Griffith, Dr. L. Guthrie, Mr. Raymond Johnson, Dr. Maclure, Mr. L. Mark, and Mr. Knowsley Thornton.

After the meeting a conversazione was held, at which a large number of members and guests were present. Much interest was shown in a collection of skiagrams lent by Mr. William Anderson, Mr. W. H. Battle, Dr. Barry Blacker, Mr. H. T. Butlin, Mr. Percy Dean, Mr. Pearce Gould, Dr. W. S. Hedley, Mr. Victor Horsley, Mr. C. B. Keetley, Dr. Leon, Dr. Laurie, Dr. Macintyre (Glasgow), Dr. MacClure (Cromer), Mr. Howard Marsh, Mr. Henry Morris, Mr. Pitts, Mr. Noble Smith, Mr. Bland Sutton, Dr. John Shaw, Dr. G. A. Sutherland, and Dr. St. Clair Thomson. Dr. Hedley and Dr. H. Campbell Thomson gave a series of demonstrations with the fluorescent screen during the evening, and the meeting was also entertained by the artistic singing of Mr. Gilbert Denis and Mr. Mervyn Dene, and the violin solo of Dr. Haydon, Mr. Frank Barat being at the piano. A small orchestra filled in the intervals with selections by popular composers.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases, Specimens, and Skiagraph.—Foreign Body in the Œsophagus.

A MEETING of this society was held on Jan. 14th, the President, Mr. RECKLESS, being in the chair.

Dr. R. F. CASTLE showed a man, aged fifty years, suffering from Labio-glosso-pharyngeal Paralysis. The course of the disease was the reverse of the usual one, since the muscles of the larynx were the first to be affected instead of the last.

Mr. H. LOCKWOOD showed a Vesicular Mole weighing 2½lb. passed by a woman, aged forty-four years, the mother of nine children, who went the full normal period of pregnancy. There was considerable hæmorrhage four or five months after the last menstruation, but the large mass was passed

Hosted by Google

without any complication and the woman made a good recovery.

Mr. LOCKWOOD also related a case of Foreign Body (False Teeth) in the Œsophagus. A hard substance was encountered at the junction of the œsophagus and pharynx, and after some difficulty and considerable hæmorrhage Mr. Lockwood extracted a palate with ten teeth attached. No complication ensued.

Mr. ARCHIBALD CUFF showed: 1 A Skiagraph of the Bones after an extensive Compound Fracture of the Leg. The fragments of the tibia were united with silver wires. The wound had perfectly healed in three weeks, and the after-result was good. 2. (For Mr. G. H. SHAW) an Enterolith which had caused acute intestinal obstruction in a woman aged fifty-nine years. The obstruction had lasted four days and the patient was much exhausted. The stone was removed by laparotomy, but the patient never rallied from the shock. The enterolith, which was of brownish-grey colour, measuring about one and a half inches by three-quarters of an inch, appeared to be a compound of salts of lime and magnesium, combined with fæcal matter. 3. A Calculus which had been impacted at the junction of the membranous and penile portions of the urethra of a boy aged ten years. The stone was cut down upon and removed and the skin brought together with silkworm gut. A catheter was retained for two days. The patient left the hospital recovered on the tenth day.

Dr. SINCLAIR WHITE showed four cases of successful Trephining. The first case, that of a man aged twenty-five years, was undertaken for the relief of traumatic epilepsy with mania. The patient, who had been an inmate of Wadsley Asylum, was operated on eight months ago. There had been immunity from the fits and mania since the operation. The second case was that of a child, aged four years, who began to have convulsions three hours after an injury to the left temple. The convulsions commenced on the left side of the face and rapidly spread to the left arm and leg. They were continuous, and the child was quite unconscious. The wound on the left temple was first explored, and a fracture being detected the trephine was applied, but without benefit. A large trephine disc was next removed over the region corresponding to the centre of the right Rolandic fissure, when the fits ceased immediately and permanently, and rapid recovery of consciousness followed. The third case was one of compound, comminuted, and depressed fracture of the right side of the frontal bone caused by a small rapidly revolving wheel starting from its bed. The inner table was much more extensively fractured than the outer. About thirty pieces of bone, several of which were lodged in the brain, were removed. The chief interest of the case lay in the fact that the patient, an adult male, went about for a fortnight after the injury, apparently without much discomfort, before the operation was done. The fourth case was one of cerebral abscess in a boy, aged twelve years, due to a wound in the forehead which had been inflicted three weeks previously. The skull was not fractured. The abscess contained about an ounce of pus and was situated on the surface of the right frontal lobe. The symptoms were headache, gradual onset of stupor, choked optic disc, rapid wasting, and subnormal pulse and temperature.

Dr. SINCLAIR WHITE also showed a case of Aneurysmal Varix between the Superior Thyroid Artery and the Anterior External Jugular Vein on the right side in a man aged thirty-eight years. The vein was much dilated and pulsated freely. The abnormal communication was marked by a small collapsable swelling. The thrill was very distinct and the bruit very loud. The condition caused little inconvenience and it was thought best to leave it alone.

The PRESIDENT, Dr. BURGESS, Mr. SNELL, Dr. KEELING, Mr. PYE-SMITH, Mr. CUFF, and Dr. ADDISON made remarks.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

Treatment of Nævi by Electrolysis.—Exhibition of Cases and Specimens.

A MEETING of this society was held on Jan. 20th, Dr. W. B. RANSOM, President, being in the chair.

Dr. L. W. MARSHALL read a paper on the Treatment of Nævi by Electrolysis and referred to an article by him which appeared in THE LANCET of Jan. 12th, 1889. He stated that the opinions then expressed were strengthened by the continued use up to date of this method. Before dealing with the treatment of nævi by electrolysis Dr. Marshall reviewed the several methods most commonly in use—viz., ligature, excision, injection, and the various applications such as ethylate of sodium, nitric acid, &c. These were all condemned with the exception of excision, the use of which he confined to nævi on unexposed parts which were not too large to admit of its adoption. It was claimed for electrolysis that it was (1) free from pain after operation; (2) it was free from danger; (3) no bleeding occurred; and (4) the scar which remained was whitish in colour and more nearly resembled true skin than any other. There was no tendency to contraction of this scar. The one argument against its use was its tediousness. Dr. Marshall insisted on the fact that it was only necessary to stay the growth and nature would complete the process. Too frequent operation was deprecated, and as an illustration of the time likely to be occupied before a good result was gained it was stated that two years would elapse before a raised nævus on the eyelid would yield a perfect cure. The great value of Lewis Jones' bi-polar needle was pointed out. Dr. Marshall believed that a cure was effected by plugging of the vessels and subsequent contraction by the formation of fibroid bands. He always aimed at attaining the former by attacking the base first. The use of a galvanometer was negatived, and it was pointed out that by change of colour alone could a safe guide be found as to the strength of current to be used and the period of its application. Dr. Marshall also stated that he could form no opinion as to the number of operations required for a given nævus until he had gauged the resistance by an operation. The history was given of an enormous raised nævus on the loin of a baby seven months old, which measured after the second operation six and a half inches by three and a half inches. This nævus was stopped completely in three operations. Eight cases were shown, all of which bore out the statements made in the paper, but the paper was based upon twenty years' experience of electrolysis for nævi. — Dr. PESKETT, Mr. O'MULLANE, the PRESIDENT, Dr. TRESIDDER, and Miss GREY spoke and asked questions, and Dr. MARSHALL replied.

Dr. MARSHALL also showed a boy, aged thirteen years, upon whom he had operated for Harelip and Cleft Palate; also Photographs from a very successful case of Osteotomy.

Dr. RINGROSE showed a man, aged thirty-four years, suffering from Keratosis Pilaris. He pointed out the distinctions between this disease and lichen pilaris.

Mr. LAWS showed a specimen of Glioma of the Retina occurring in a child, aged three years, with a six months' history. Strabismus was the first symptom noticed and afterwards a whitish appearance on the iris existed. He also showed a macroscopic specimen of the growth.

The PRESIDENT showed a microscopic specimen of Sarcoma of the Right Lobe of the Cerebellum from a patient who had middle-ear disease and who was trephined for cerebral abscess.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Election of Officers for 1897.—Exhibition of Specimens.—The Development of the Placenta.

THE annual meeting of this society was held at Owens College, Manchester, on Jan. 15th.

Dr. Walter of Manchester and Dr. T. B. Grimsdale of Liverpool, the retiring president and secretary, were thanked for their services, and Dr. H. Briggs of Liverpool, and Dr. J. E. Gemmell of Liverpool, were elected as president and secretary in their places. The following gentlemen were elected as office-bearers for 1897:—Vice-Presidents: Dr. T. A. Helme, Dr. Archibald Donald, Dr. T. B. Grimsdale, Dr. Glynn Whittle, Dr. T. Kilner Clarke, Mr. Edmund Robinson, Mr. Richard Favell, and Dr. A. H. Laver. Honorary Treasurer: Mr. J. Nelson Cregeen. Council: Dr. E. Annacker, Mr. F. A. E. Barnardo, Mr. Owen Bowen, Dr. S. Buckley, Sir R. M. Craven, Dr. E. T. Davies, Dr. Duncan Forbes, Dr. H. A. Lediard, Dr. John W. Martin, Dr. T. W. Napier, Dr. J. J. O'Hagan, Dr. Lloyd Roberts, Dr. G. J. Robertson, Mr. S. Rumboll, Dr. Benjamin Scott, Dr. W. J. Sinclair, Dr. A. Stookes, Mr. G. W. Thomson, Dr. Arthur Wallace, Dr. W. K. Walls, Dr. W. Walter, and Mr. C. J. Wright. Honorary Local Secretaries: Dr. John Scott, Manchester; Mr. W. Fingland, Liverpool; Mr. Edward

Hosted by Google

O. Croft, Leeds; Dr. David Lowson, Hull; and Dr. Hugh Rhodes, Sheffield.

Dr. BRIGGS related two cases of Abdominal Hysterectomy for Uterine Fibroids, and showed the tumours.

Dr. J. E. GEMMELL related a case of Intra-uterine Disease and showed microscopic sections of Curetted Fragments.—A discussion took place as to whether the disease was adenoma uteri, benign or malignant.

Dr. W. E. FOTHERGILL read a note on the Development of the Placenta, and on its fate when retained *in utero* after the death of the fœtus; and showed several microscopic sections and drawings illustrative of the subject.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

The Death of Mr. Broadbent.—Congratulations to Lord Lister.—Exhibition of Cases and Specimens.

A MEETING of this society was held on Jan. 14th, the President, Mr. WILLIAMSON, being in the chair.

A vote of sympathy with his relatives on the occasion of the death of Mr. Samuel W. Broadbent was carried.

It was proposed and unanimously carried that the congratulations of the society be sent to Lord Lister.

Dr. HUME showed a case of Sarcoma of the Kidney. The patient, aged fifty-three years, was well till August last and then felt an uneasy dragging in the right side, noticed an increased frequency in micturition, and discovered a lump in the abdomen. On admission to the infirmary the tumour was very moveable and could be passed across from the right lumbar and iliac regions, where it mostly lay, to the left of the spinal column. Because it seemed to be tied to a pedicle to the right side, high up, and because of the absence of colon note behind the tumour and its presence in front, it was considered to be probably renal. There was nothing abnormal in the urine. The abdomen was opened in the middle line and the diagnosis verified. The median incision was extended outwards through the right rectus abdominis muscle and the tumour and kidney were removed. The whole of the anterior abdominal wound was closed and a drainage-tube inserted through the loin. The specimen (exhibited) was a sarcoma about the size of a cocoa-nut, grown from, and involving, the lower end of the kidney. Its mobility was explained by the fact that it had dragged upon, and elongated, the kidney which formed its pedicle.

Dr. HUME also showed a patient after Excision of the lower end of the Humerus for Fracture and Dislocation (Heron Watson's operation). He was a young man whose elbow had been stiffened in consequence of a fracture-dislocation proved by skiagraph (exhibited). The arm was rendered practically useless by the accident, and attempts to remedy the condition by manipulations under chloroform had failed. The lower end of the humerus had been excised by Heron Watson's method with a satisfactory result.

Dr. HUME further showed a woman on whom four Abdominal Sections had been performed—viz., an operation for removal of two Fallopian tubes four years ago, a ventral hernia resulting. She was twice operated upon by the surgeon who performed the first operation without success. Six weeks previously Dr. Hume had opened her abdomen for the fourth time to cure the ventral hernia, and the result so far was perfectly good.

Mr. PAGE showed the following specimens:—1. A large Uric Acid Calculus the size of a Tangerine orange, successfully removed by Supra-pubic Lithotomy from a man aged fifty years, who had symptoms of stone for forty years. 2. Eight Calculi of Various Sizes removed successfully by the Supra-pubic Operation from an old man with Enlarged Prostate. It was evident from the examination of the specimens that some of the calculi had undergone spontaneous fracture. 3 An Oxalate of Lime Stone the size of a Walnut successfully removed from a boy aged four years by Supra-pubic Lithotomy. 4. A Gall-stone from the Cystic Duct the size of a filbert which had been removed by operation from a young woman who had a tumour in her abdomen about the size of an ostrich egg. The tumour was freely moveable and could be placed in any part of the abdomen, but when undisturbed remained in the right side. The diagnosis being uncertain her abdomen was opened in the right linea semilunaris and the enormously distended gall-bladder was opened and emptied of a clear, colourless fluid. The cystic duct was firmly plugged by the stone (exhibited) and had to be incised for its removal. The wounds in the gall-bladder and the duct were closed by sutures and returned to the abdomen, which was entirely closed without drainage. This was the fifth case in which he had closed one or other of the ducts by suture and returned them into the undrained abdomen, and all the cases had recovered well. 5. One lobe of a Thyroid Gland removed from a female for Sudden Hæmorrhage into its Substance. The patient had noticed a small swelling for many years, which, however, caused no inconvenience. A few days before her admission to hospital whilst working hard the swelling suddenly increased in size and became painful. At the same time she had such a serious attack of difficulty in breathing that it was thought she might not recover. Since then she had other attacks of dyspnœa and the tumour (exhibited) was removed. On section it was seen that the whole substance of the tumour was infiltrated with coagulated blood, and careful examination showed at one portion of it a small ruptured cyst. It seemed a probable explanation that hæmorrhage had first occurred into the cyst and that had burst.

Mr. RUTHERFORD MORISON showed a series of specimens of Uteri illustrating conditions which he thought could be best dealt with by vaginal hysterectomy. Cancer of the body and cancer of the cervix uteri were the most common indications for the operation. In one case he had excised the uterus and a fibroid of the anterior wall the size of a cocoa-nut which was causing gradually increasing bladder trouble, with attacks of urinary retention. In one case he had excised the uterus, both tubes and one ovary for acute gonorrhœal endometritis, salpingitis, and pelvic abscess. In one case he had removed the uterus in an apparently hopeless case to allow efficient drainage of a huge pelvic abscess which had been previously drained by the abdomen and which was complicated by fæcal fistula. He thought that no preliminary treatment of the vagina and the uterus was useful. All necessary preparations could be made immediately before the operation whilst the patient was anæsthetised. He did not use any ligatures, but secured the broad ligament in hæmostatic forceps before dividing each portion, using from twelve to twenty-four pairs of forceps for this purpose. No drainage-tubes or sutures were necessary, drainage being effected by a strand of gauze passed up the centre of the forceps. The vagina was then so full that neither intestines nor omentum could escape. The forceps were left in for forty-eight hours and the gauze removed in seventy-two hours. Unless the discharge became fœtid no further treatment than keeping the external parts clean and dressed was employed. He had performed this operation nineteen times for cancer and seven times for other conditions. All the twenty-six patients had recovered and only in one case had there been any accident. In this case sharp bleeding followed the removal of the forceps at the end of twenty-four hours.

Dr. COLEY exhibited examples of Congenital Disease of the Kidney which were removed (post mortem) from a man, aged forty-two years, who died in the infirmary. His illness began a year previously with diarrhœa and vomiting. On admission he was uræmic; his urine contained blood, and the two large tumours (exhibited) were found in his abdomen. They very closely resembled in appearance certain multilocular cystic ovarian tumours.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.

A MEETING of this society was held on Jan. 22nd, the President, Dr. W. L. REID, being in the chair.

Dr. LINDSAY STEVEN showed the parts from a case of Abdominal Aneurysm which had arisen from the posterior aspect of the aorta and had ruptured into the tissue behind the peritoneum.

Dr. H. E. JONES showed a number of specimens of Urine from a case of Paroxysmal Hæmoglobinuria, illustrating the rapidity with which the blood-colouring matter may disappear from the urine. The fact that the patient was a young woman was another feature of interest.

Dr. LINDSAY STEVEN and Dr. T. K. MONRO demonstrated four cases of Muscular Atrophy. The first two followed the usual type of progressive spinal muscular atrophy, the one

Hosted by Google

being an advanced and the other an early case; in the latter the atrophy was confined to the muscles of the right hand. The third patient was a girl in whom there was atrophy of the right trapezius and serratus magnus, and the condition was attributed by the patient to the act of carrying heavy weights. In the fourth case the patient, a young man, had been crushed by a coal truck, and there were atrophy and weakness of the muscles of the back, manifested by lordosis and inability to rise from the recumbent posture; in addition, the muscles of the right upper arm were much atrophied. All the patients had been treated with hypodermic injections of nitrate of strychnine and with evidences of improvement—at least, to the extent of apparent staying of the atrophic changes.

Dr. J. CARSLAW and Dr. R M. BUCHANAN submitted a report on a case of Double Facial Paralysis, and showed a number of microscopic sections of the nerves. The patient, a man aged thirty-two years, had suffered from syphilis (chancre) nine months before the paralysis appeared, but the onset of the paralysis was immediately preceded by exposure to severe cold. He improved to some extent under anti-syphilitic treatment. Shortly after treatment was commenced, however, he suddenly became paralysed (left hemiplegia), and died in the course of a few days. After death a limited softened area was found in the right corpus striatum, and the sections submitted showed considerable hæmorrhages under the sheaths of the facial and auditory nerves and some cellular proliferation. Similar changes were present in the perivascular spaces in the neighbourhood of the softened area in the brain. The case was regarded as of great importance in the possible interpretation it afforded of the exact nature of the changes to which the nervous system was liable in early syphilis.

Dr. W. G. DUN and Dr. LINDSAY STEVEN gave an account of a case of Congenital Cardiac Disease and showed the heart, which displayed extreme stenosis of the pulmonary artery, with patency of the foramen ovale, but without any imperfection of the inter-ventricular septum. The child at the time of death was four years of age and no symptoms exciting the suspicion of cardiac disease had been observed until within the last year of life. Attention was drawn to the late arrival of cyanosis and cardiac embarrassment, to the perfection of the inter-ventricular septum, and to the extreme contraction of the orifice of the pulmonary valve, and it was urged that such a conjunction of events justified the view that the disease must have commenced comparatively late in intra-uterine life and have continued to progress after birth. The abnormal communication between the right heart and the systemic circulation being limited to a moderate opening at the foramen ovale, whilst the degree of cyanosis had latterly been extreme, the case lent force to the suggestion that the cyanosis in such conditions was not due to mingling of venous with arterial blood, but rather to inefficient aeration of blood as a consequence of the pulmonic obstruction.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

Pathological Conditions of the Heart.—Achorion Schönleinii.—Pyogenic Organisms.—Trichinosis.

A MEETING of this section was held on Jan. 15th, Professor BENNETT being in the chair.

Dr. J. B. COLEMAN exhibited ten specimens of Pathological Conditions of the Heart. One was the heart of a boy, aged eight years, who suffered from mild chorea and mitral regurgitation of old standing. Whilst in the hospital he developed acute endocarditis, from which he died. His heart was remarkably enlarged, particularly the left side. The mitral orifice was much dilated, admitting two fingers readily, whilst the apex was bifurcated, the apex of the left ventricle being nearly an inch below that of the right and separated from it by a groove. Another specimen was taken from a girl, aged nineteen years, who had been under Dr. Coleman's care from time to time for the past two years, presenting well-marked signs of mitral stenosis. The heart shewed extreme stenosis of the mitral orifice, which would not admit the edge of the finger-nail. The left auricle was much hypertrophied, the left ventricle was of normal size, the right ventricle was hypertrophied, and the right auricle dilated. The patient had suffered from paroxysms of dyspnœa and hæmoptysis, and hæmorrhagic infarcts were found in the lungs. Another specimen was from a man, aged sixty-six years, who was dead on admission to hospital. There was a rupture near the apex of the left ventricle. On the pericardial surface there was a rent about half an inch in length and on the corresponding endocardial surface there was ulcerative destruction of the endocardium and muscular tissue. The pericardium was distended with blood. The last specimen was taken from a labourer, aged twenty-eight years, who, whilst engaged in some severe work on the quays, suddenly dropped dead. The men who brought him to hospital stated that previously he had made no complaint. The pericardium was distended with blood, and the cause of death was a ruptured aneurysm of the left ventricle somewhat bigger than a walnut and situated near the apex of the ventricle. The external wall of the aneurysm was composed of the pouched-out pericardium; the cavity invaded the thickened myocardium, and a small opening from the inner side of the ventricle near the apex led into the sac of the aneurysm.—The CHAIRMAN remarked that these cases of spontaneous rupture of the heart accorded with the opinion, expressed by Dr. Stokes in former days, that when spontaneous rupture of the heart occurred it took place at the apex of the left ventricle.—Dr. MCWEENEY said he had examined a large number of hearts, but had never seen anything like the heart with the double apex which had been exhibited. Occasionally a slight depression between the right and the left sides of the apex was met with; but a left apex fully an inch below one on the right side, with a deep groove running between them, was a matter of considerable rarity.

Dr. MCWEENEY showed pure cultivations on glycerin agar and ordinary agar of Achorion Schönleinii grown from a favus scutulum given him by Dr. Coleman. A fragment of the scutulum was crushed in a drop of sterile broth between sterile glass slips, and a trace of the fluid rubbed into the nutrient surfaces. Abundant and pure development occurred at 37° C.

Dr. MCWEENEY also showed a series of Pyogenic Organisms which he had recently isolated from the human subject. The first was streptococcus pyogenes *var.* longus from a severe whitlow on his own finger (due to dissection). The second was staphylococcus aureus from a metastatic miliary abscess of the kidney in a case of septico-pyæmia and infective endocarditis that had terminated fatally within two days of admission to hospital. The patient was a powerfully-built man, aged twenty-five years, of alcoholic habits. The third organism was bacterium coli commune from the peritoneal exudation of a case of general purulent peritonitis from perforation of the vermiform appendix in a boy aged ten. A remarkable feature was the discharge of four ounces of turbid, yellow, foul-smelling fluid from the subject's left ear when on the post-mortem table. This fluid contained bacterium coli also in pure cultivation (specimen shown). Intra-cranially nothing was found to account for the aural discharge. Lastly, he showed bacillus pyocyaneus obtained from the urine of a case resembling tuberculous pyelitis, but shown to be due to infection of the kidney with the organism mentioned. This was a rare occurrence. The bacillus isolated was intensely chromogenic and pathogenic.

Dr. ALFRED R. PARSONS made a communication on Trichinosis, which was illustrated by specimens of encapsuled trichinæ removed from the body of a patient between sixty and seventy years of age, who was admitted to the City of Dublin Hospital last September. He was a labourer by occupation, and he stated that he had never had any serious illness. For a few years past he has had a cough, but was not obliged to give up his work till six or seven weeks before admission. Physical examination revealed the presence of extensive tuberculous disease of the right lung. The case terminated fatally in a little more than two months after his admission and the post-mortem examination disclosed a large cavity in the apex of the right lung. Scattered through the muscles, especially of the neck, extremities, and diaphragm, were numerous white spots, most abundant towards the tendinous insertion of the muscles. A small portion of one of the muscles was spread out in a thin layer on a slide, and in an area about half an inch square at least twenty-five capsules could be counted. None could be

Hosted by Google

found in the heart muscle. On treating the capsules with dilute hydrochloric acid the embryonic trichinæ were easily seen. Experimental investigation proved that the trichinæ were dead, and probably the attack occurred so many years ago that it had passed out of the recollection of the patient. It would have been impossible for such an invasion of the muscles as this case disclosed to have occurred without producing symptoms. Within the last five years trichinæ in muscle have been recognised in two other cases—one in the anatomical department of Trinity College and the other in the anatomical department of the Royal College of Surgeons in Ireland.—The CHAIRMAN said the name of Dr. Robert Harrison of that city ought to come into the literature of this subject, for he reported the figure of trichina spiralis synchronously with, if not previously to, Professor Owen.—Dr. FRAZER said that the name of Dr. Robert McDonnell should also come into the history of the subject, for he had a case of trichina, and fed white rats with the infected tissue.—Dr. FINNY said that about the year 1867, when he was Demonstrator in Trinity College, he came on a portion of a diaphragm which was studded over with these white spots; and on examining them he failed to find anything but calcareous-covered trichinæ. The patient was an old woman, and it had not appeared that she suffered in any way from them. How long these organisms remained in the calcareous state after they accomplished their final journey into the muscular tissues was still unknown.—Dr. PARSONS, in reply, said that in neither the English nor the German literature of the subject did the names of Dr. Harrison or Dr. McDonnell occur. How long these organisms retained their vitality after they had become encapsuled had not been determined. It was certain, however, that they did retain vitality for a considerable time after they were encapsuled, and that dipping them in alcohol did not destroy them. In the early stages the symptoms produced by them might easily be mistaken for enteric fever, for there was pyrexia for five or six weeks, but later there was a change in the symptoms, and the severe pains in the muscles indicated the lodgement of the embryos in them and the consequent irritation.

Reviews and Notices of Books.

A System of Surgery. Edited by FREDERIC S. DENNIS, M.D., Professor of the Principles and Practice of Surgery, Bellevue Hospital Medical School, assisted by JOHN S. BILLINGS, M.D., LL.D. Edin. and Harvard, D.C.L. Oxon., Deputy Surgeon-General, U.S.A. Vol. III. Pp. 919. Philadelphia: Lee Brothers and Co. 1895. Price $6.

THE third volume of this excellent system of surgery maintains the high standard reached by its two predecessors. In it we find the same comprehensive treatment of the subjects with which it deals.

Most of the articles in this volume are rather short, but the paper on the Surgery of the Genito-Urinary System extends to over three hundred pages; this is by Professor J. W. White of Philadelphia, assisted by Dr. W. H. Furness. As might have been expected from the names of the authors we are presented with an admirable account of the subject. This article contains many references to authorities, and in this respect differs markedly from the other contributions in this volume, for most of them are singularly bare of references. There are a few points in Professor White's paper which call for notice. In the description of puncture above the pubes for retention of urine it is mentioned that a trocar and cannula are employed, so that when almost immediately afterwards Cock's perineal puncture is referred to the reader would be led to think that this operation also was done with the same instruments, whereas it is performed with a bistoury. In the account of cystoscopy the author points out that by observing the openings of the ureters it is possible to see if either kidney has ceased to secrete, or if the urine from either kidney is turbid with blood or pus—matters of great importance in deciding on the advisability of performing nephrectomy or any other operation on the kidney.

In dilating the bladder preparatory to the performance of suprapubic cystotomy we think it is difficult to estimate, as is suggested in this article, the amount of fluid which may be safely injected by the resistance felt in working the syringe; this is a very fallible, and therefore very dangerous, guide. The only safe method to employ is to dilate the bladder by hydrostatic pressure, using a funnel and tube; if the funnel be not raised more than four feet above the body of the patient the pressure on the bladder wall cannot exceed two pounds per square inch; this is a pressure which is quite sufficient to overcome vesical spasm, but any pressure much greater than this is unsafe with damaged walls of the bladder. Dr. White employs the term "canal of Nuck" for the processus vaginalis in the male; we are inclined to think that this term has hitherto been restricted to the corresponding structure in the female. We find the theory still put forward that the greater frequency of left-sided varicocele is connected with the angle at which the left spermatic vein joins the renal vein; we do not think that this ancient theory can really be maintained; the pressure of an overloaded sigmoid flexure is a much more probable cause.

The operation of castration for senile hypertrophy of the prostate was introduced by Professor White, and he gives a full account of this method of treatment of this troublesome condition.

Professor D. B. Delavan of New York has contributed a very satisfactory article on the Surgery of the Larynx and Trachea. The only other paper of any length is that on Syphilis, by Dr. R. W. Taylor of New York. The question of the mode of action of mercury in the treatment of syphilis is no doubt a difficult one, but we cannot agree with the author when he says that "we know by inductive reasoning and observation" that mercury "acts by destroying and rendering fit for absorption" the small-celled infiltration which is the first stage of all syphilitic lesions; and also when, acting on this view, he advises that mercury should not be given until this infiltration has occurred—that is to say, until the secondary stage has declared itself. It is generally, we believe, admitted that mercury acts directly on the disease, either on the organism itself, to the presence of which syphilis is due, or on the toxins which are formed; and the evidence is sufficient that if mercury be given early secondary manifestations do not appear at all or are very slight and transient. In the article on the Diseases of the Salivary Glands, by Professor C. B. Porter of Harvard University, it is stated that in mumps there is a tendency to metastasis to the ovaries. The statement is certainly to be found in most text-books, but we are not aware of any case ever having been reported in which this metastasis has occurred; it has probably crept into the book as analogous to the well-known metastasis to the testes.

Dr. Willard Parker of New York commences his account of the surgery of the neck by an excellent description of the development, which will make it very easy for the reader to understand the somewhat complex subject of the congenital abnormalities of that region.

In the account of the surgery of the chest, contributed by the editor, we are told that it is dangerous to wash out the pleural cavity after tapping an empyema, as hemiplegia may result. This is true, but a still graver result may follow, for in by no means a few cases fatal syncope has occurred, probably due to the injected liquid being too cold. In hernia of the lung it is surely hardly necessary for Professor Dennis to tell us that "this variety of hernia has no peritoneal sac." Numerous black and white illustrations accompany the articles, and there are also several in colours; of these latter the most noteworthy is one representing an interesting case of carcinoma lenticulare.

Hosted by Google

Kurzgefasstes Lehrbuch der Mikroscopisch-Gynäkologischen Diagnostik. Von Dr. JOSEF ALBERT AMANN, Jr., Privatdocent der Gynäkologie an der Königlichen Universität, München. Mit 94 Abbildungen. (*Concise Text-book on the Use of the Microscope in Gynæcological Diagnosis.* By Dr. JOSEF ALBERT AMANN, jun., Tutor on Gynæcology at the Royal University, Munich. With 94 Illustrations.) Wiesbaden: J. F. Bergmann. 1897. Pp. 172.

IT is interesting to find that the value to the student of the examination of both macroscopic as well as of microscopic characters of all forms of disease, whether common or rare, is becoming so well recognised that special treatises on most of the organs of the body devote a chapter to the modes of preserving, cutting, staining, and mounting specimens. The present volume is intended to supply the student who is beginning gynæcological work with information in regard to the means at his disposal for the diagnosis of uterine disease, and accordingly commences with a short account of the methods in ordinary use in pathological laboratories and their application to the microscopic examination of abnormal conditions of the fluids and solids of the generative apparatus. Dr. Amann commences with a description of the staphylococci and streptococci, and of the micro-organism which is by far the most commonly found in the generative tract, the gonococcus; and the far less frequent but still common bacterium coli. The vaginal secretion, the author remarks, is acid and contains epithelial cells, yeast cells, cocci, and bacteria, and it is interesting to find that the vagina is a very unfavourable soil for pathogenic germs since the secretion from its glands possesses powerful germicide properties. Hence pathogenic germs are rarely found in it and when present have greatly reduced virulence. If the vaginal secretion be alkaline it is abnormal and then often contains pus cells, diplococci closely resembling gonococci, leptothrix filaments, and occasionally the trichomonas. As an illustration of the mode in which the author deals with his subject we venture to translate a portion of the section on the physiological changes of the uterine mucous membrane, that portion which deals with menstruation and which may prove interesting to our readers: "The changes that take place in the mucous membrane of the uterus during menstruation are of a passive nature and are simply caused by the increased afflux of blood. Shortly before menstruation a serous infiltration appears to be produced by the simple congestion of the vessels in the membrane. The vessels are indeed very greatly distended and the thin-walled capillary plexus surrounding the superficial part of the glands ruptures at various points, and the blood is effused into the wide-meshed and delicate stratum proprium just beneath the investing epithelium. The lacunæ of this lymphoid tissue are soon distended with the escaped blood, causing a partial breaking down of the tissue and patches of ecchymosis of various size are found in the stratum proprium. The cement substance of the investing epithelium still holds, but at length, after being much raised and stretched, it gives way and is in part thrown off. The gland tubes may frequently be seen isolated from their surroundings by masses of blood, and in their lumen red corpuscles may be found which have entered it from the mouth, and also, when the glands have been torn away, from the deep-torn surface. The diapedesis of leucocytes does not amount to a small-cell infiltration. The uterine contractions that result from the presence of blood in its cavity facilitate the discharge of that fluid with the detached external portion of the mucous membrane. The greater part of the membrane is preserved, though it appears to undergo a partial fatty degeneration. No renewal of the epithelium or of the elements of the stratum proprium occur whilst menstruation is progressing, and no indications of mitosis have been observed in these parts at this stage. The changes that take place, then, in the normal mucous membrane consist in mechanical compression, disintegration, and detachment of the superficial layers of the mucous membrane. As the congestion passes off a rapid regeneration of the mucous membrane occurs and mitosis may then be observed in the gland epithelium and in the cells of the stratum proprium and in the endothelial cells of the vascular walls. In the course of ten or twelve days the restoration of the mucous membrane is complete and the resorption of the ecchymosed blood has been accomplished."

The characters presented by the mucous membrane in dysmenorrhœa and in pregnancy are then given with a differential diagnosis of decidua menstrualis, decidua graviditatis intra-uterinæ, and decidua graviditatis extra-uterinæ.

A good account of the Fallopian tubes is given both in normal and diseased conditions, a subject that is scarcely more than mentioned even in Müller's "Handbuch." The text is here, as throughout the work, accompanied by original and well-executed illustrations that will prove useful to the student. The work is a reliable one and may be read with advantage by all who are devoting themselves to this branch of study.

The Causes and Treatment of Rheumatoid Arthritis. By SAMUEL HYDE, M.D. St. And. London: John Bale and Sons. 1896. 3*s.* 6*d.*

THE exceptional opportunities that many years' practice in Buxton have afforded Dr. Hyde of studying cases of rheumatoid arthritis and watching the results of its treatment make the expression of his view worthy of every consideration and study. This work contains much that is original and will well repay perusal. Rheumatoid arthritis is a disease the etiology and pathology of which has been much debated and which is extremely difficult to treat with any satisfaction. Dr. Hyde discusses the various views which have been advanced as regards the causes of the disease and defines it as "a trophoneurosis of joints unassociated with any systemic disorder and probably dependent upon some central nervous lesion." He is strongly inclined to believe that a central nervous lesion constitutes the starting-point in the majority of pronounced and characteristic cases of the disease. He states that in his experience no causes are more productive of this distressing malady than certain psychical conditions associated with anxiety and mental distress. The author's views on the morbid anatomy of rheumatoid arthritis are also plainly stated. He considers that the changes which occur in the structure of the joint are, on the whole, due to abnormal nutrition, and that the process may be in some cases associated with an inflammatory process, but not necessarily so.

In the chapter on "Pathology" the nervous element is again insisted on; the author says: "The more this factor in the causation of the disease has been recognised and allowed to influence my treatment the more I have been encouraged by the results." The treatment of this affection is considered very fully, occupying half the book—drugs, diet, clothing, massage, the use of stimulants, baths and mineral waters, climate, and the use of animal extracts. Great stress is laid on a full, generous diet, not too stimulating, and arranged with due regard to the digestive conditions of each particular case. Alcohol is not only admissible, but often a desirable factor of diet. The chapter on baths is also interesting and instructive.

We can cordially recommend this short work to our readers, believing that they will find much help in the comprehension and treatment of a disease the victims of which are so numerous and which so frequently results in permanent disablement.

LIBRARY TABLE.

Dod's Parliamentary Companion. London: Whittaker and Co. 1897. Price 4*s.* 6*d.*—The issue for the present year

Hosted by Google

of this most useful little book comes opportunely at the time of the re-opening of Parliament. That it is literally brought "up to date" is shown by the fact that in the appendix is to be found an announcement of the peerage conferred as a New Year Honour on Sir Joseph Lister. The editor, though he states that the new title is not yet announced, sagely assumes in an accompanying slip that the family name of Lister will be adopted. As our readers are aware we were able to announce in our issue of Jan. 16th that the first medical peer would take the title of Lord Lister. By the death in 1895 of Dr. Daniel Ambrose, member for South Louth, and the resignation in March, 1896, of Mr. J. E. Kenny, member for the College Green division of Dublin, the number of medical men who obtained seats in the House of Commons at the General Election held in July, 1895, was reduced by two. On the other hand, the subsequent election of Sir William Overend Priestley, M.D., as member for Edinburgh and St. Andrews Universities introduced another representative of the medical profession into Parliament. So far as we are able to verify, the details given in the present issue of Dod's Parliamentary Companion are, as usual, reliable.

JOURNALS AND REVIEWS.

The Monist.—The January number opens with an abstruse metaphysical paper, fifty pages in length, on the Logic of Relatives. Under the head of Relatives of Second Intention the author, Mr. Charles S. Peirce of New York, explains that "logic in this stage of development may be called paradisaical logic, because it represents the state of Man's cognition before the Fall." Dr. P. Topinard of Paris gives the third of his series of articles on Science and Faith. On the present occasion he discusses the subject of Animal Societies, especially the assemblage of fishes in shoals and of birds and quadrupeds in flocks or herds.

The Psychological Review.—The January number contains two papers of considerable physiological interest. Professor W. L. Bryan and Mr. Noble Harter, both of Indiana University, give the results of their investigation of various problems connected with the acquisition of the telegraphic language, based on an analysis of the performances of numerous telegraphic operators, both learners and experts. MM. A. Binet and N. Vaschide of Paris describe experiments on the Influence of Intellectual Work on the Blood-pressure in Man. Their apparatus was a Mosso's sphygmomanometer, registering the pulsations of two fingers of each hand placed in indiarubber finger-tubes and exposed to the pressure of water. With this instrument it was found that when a young man mentally multiplied two figures by two figures "the first three or four pulsations which register themselves are usually of the same character as the preceding; sometimes they are slightly shortened. ..... Then the pulsation increases; it doubles in size or becomes twice and often three times as great."

Medicine (Detroit).—Dr. J. Frank of Chicago describes a new contrivance for intestinal end-to-end anastomosis. It consists of two decalcified bone collars, stitched one to each end of a piece of indiarubber tubing, which fits the aperture of the collars and is of such a length that the collars touch one another. The cut ends of the intestine, apposed and encircling the line of contact of the collars, are pressed in between them, slightly stretching the indiarubber tube; the elasticity of the indiarubber keeps the parts in position, and the tube is eventually passed with the fæces.

Birmingham Medical Review.—The opening paper is a practical and suggestive article on the importance of the Study of Anatomy by Mr. W. F. Haslam who introduces a good many useful hint on the work of the dissecting room and much profitable advice as to the cultivation of the faculties of observation and memory. Mr. E. Luke Freer as an illustrated paper on Operative Measures in Orthopædic Practice. Mr. J. Furneaux Jordan describes the successful reduction of a complete inversion of the uterus which had existed for more than seven months; the operation employed was that of Küstner, as modified by Dührssen.

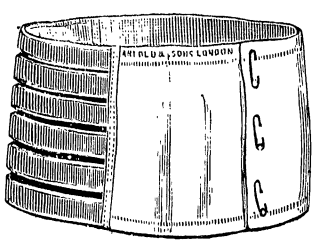
The Senate for January contains a silhouette portrait of Sir Henry Acland, late Regius Professor of Medicine in the University of Oxford. It is a very good likeness, but we have much doubt whether the silhouette can be used with advantage to depict persons past the prime of life unless the introduction of a few white lines upon the face be allowed. In young people the profile may tell the story, but in those who have put a long record of work behind them the chief character is given to the face by lines which cannot be represented in the ordinary silhouette. The contents of the journal are interesting, and, as usual, show a familiarity with modern thought and literature, but Mr. Frankfort Moore should not be classed with Sir Walter Besant as a novelist, and to say that Mr. Gale has "become as thin and mechanical as Mr. Kipling in his least interesting moods" is rubbish.

The Journal of State Medicine. Vol. V., No. 1. January, 1897. London: Baillière, Tindall, and Cox. Price 2*s.*—With the commencement of 1897 it has been decided by the council of the British Institute of Public Health to publish this journal monthly, and the number here noticed is the first issued under the new arrangement. The Council is to be congratulated on this step, which should lead to a more continuous interest in the *Journal* than was heretofore possible. The present number contains an interesting paper from the pen of Mr. A. E. Fletcher, late H.M. Chief Inspector under the Alkali Acts, on the Pollution of the Atmosphere by Coal Smoke, which sets forth in condensed form matter which will be of use to many medical officers of health. Mr. Fletcher is not sanguine as to the reduction of smoke from private dwellings, and, as he adds, "he would be a bold man who would try to persuade a Briton to give up his open fire." Dr. Vivian Poore has a paper on Dry Methods of Treating Urine for Sanitary Purposes, in which he describes the satisfactory results obtained by the reception of urine into sawdust. He advises the adoption of this method under certain circumstances in rural districts. Both the above papers were read before the Glasgow Congress of the Institute in 1896. An article on Public Health Laboratory Work in London regrets that the Metropolitan Asylums Board have terminated their arrangement for bacteriological examinations at the laboratories of the Royal Colleges of Physicians of London and Surgeons of England and have substituted for it local examinations at the several hospitals of the Board. The step is regarded as a retrograde one.

Journal of Mental Science. January, 1897.—In the current issue of this quarterly Dr. Julius Mickle continues his observations on atypical and unusual brain forms, especially in relation to mental states. Dr. Gilmore Ellis, of Singapore, describes a peculiar nervous affection called "Latah," which is common amongst the Malays. The disease is almost invariably hereditary and is characterised by symptoms of a mimetic and paroxysmal nature. A valuable and original contribution to the pathology of insanity, by Dr. John Turner of the Essex County Asylum, deals with the question of phagocytosis in the brains of the insane. The function of absorbing and removing effete and degenerate material has been ascribed by Mr. Bevan Lewis to the Deiters' cells, but Dr. Turner goes further, and attributes similar power to other bodies, which he states are wandering leucocytes. He describes and illustrates, by means of small plates, numbers of cells lying free in the pericellular spaces. Practically, in all cases where they are seen, a portion of the cytoplasm of the nerve cell in their vicinity is deficient. This piece has a clean-cut, scooped-out appearance, and if two or more

Hosted by Google

cells are present then two or more portions of the cytoplasm in their neighbourhood are scooped out. He concludes that either the invading cell exercises its solvent action on the cytoplasm of the nerve cell in its vicinity, whereby such portion is carried away by the lymph stream, or else they themselves absorb, and, as it were, feed on, the nerve cells. Doubtless this pathological condition will be further investigated, for it is by the record of such original work that a clearer understanding will be arrived at regarding much that is obscure in the pathology of mental diseases. A statistical paper by Mr. Pitcairn, of H.M.'s Prison, Holloway, shows that this institution receives in the course of a year many acute cases of insanity, which must entail much anxious work on the medical staff. In view of the rapid flow of cases the services of an additional assistant medical officer are urgently required. Dr. Walter Channing of Brookline, Massachusetts, U.S.A., writes on the Palatal Deformities of Idiots; his conclusions are not quite in conformity with the opinions expressed by various authorities in this country.



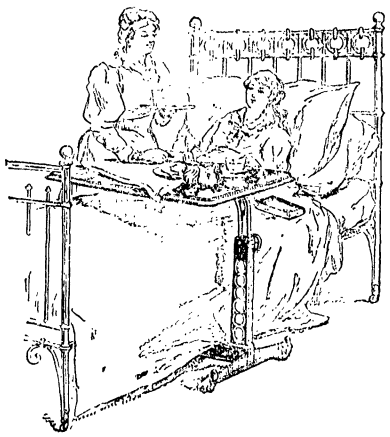
The monthly publications of the Religious Tract Society include the *Leisure Hour*, the *Girl's Own Paper*, the *Sunday at Home*, and *Sunday Hours*. The February part of the *Leisure Hour* has an interesting though short notice of the late Coventry Patmore, a poet who has treated the subject of domestic felicity with a spiritual purity and a tenderness which few if any of our singers of love have equalled. The same number also contains a sketch, illustrated with a portrait and autograph, of the author of "Wuthering Heights." The *Girl's Own Paper* is quite up to its usual standard of excellence, as is also the *Sunday at Home*. *Sunday Hours*, the new paper, contains Sunday reading for boys and girls; if the healthy tone of this latter publication is maintained it should find a place in every home where there are boys or girls or both.

Mercy and Truth.—This is the title of a new monthly periodical, issued at the modest price of one penny by the Church Missionary Society, Salisbury-square, E.C., and having as its sub-title, "A Record of C.M.S. Medical Mission Work." Dr. T. L. Pennell has an article on "The Afghans—How can we Reach them?" in which he gives some account of the work of a mission hospital. In another article the mission hospital at Hangchow is described.

New Inventions.

NEW OBSTETRIC BINDER.

AT my suggestion Messrs. Arnold and Sons of West Smithfield, London, have made for me a new form of obstetric binder which I hope will prove of use in midwifery. The novelty of its manufacture consists in a row of silk elastic bands inserted on one side of the bandage, which is itself



made of strong linen. By these means I hope to obtain the following advantages: (1) Even pressure over the abdomen, each band of elastic only expanding to the extent required at its situation; (2) power of self-adjustability by the patient; (3) the bands of elastic being at the side the patient will not be inconvenienced by having to lie on them; (4) the strong safety-pins supplied with each bandage will prove a boon to many, for often nothing is so difficult to find at these times as a pin worthy the name; (5) the binder is easily cleansed and can be used many times if carefully put away after each convalescence. I hope the time is at hand when every expectant mother will provide herself with a scientifically constructed obstetric binder and that the day of the roller-towel and any odd pins that can be found will pass away, to the improvement of the figures of the mothers and last, but not least, the temper of the practitioner.

Billesdon, Leicester. A. DUNLEY-OWEN.

THE "VICTOR GEM" INVALIDS' TABLE.

We illustrate below a new invalids' table for which are claimed some points of advantage over the old form. When not in use as a bed table the usual form of this convenience precludes its being used for any other purpose, and consequently is likely to be "in the way." The "Victor Gem," however, by its construction can be adapted for general use, and can be used as a card-, library-, sewing-table, &c. The top of the table is made in antique oak or walnut and is firmly secured by means of a small hand wheel to a right-angled framework of iron, one arm of which as

will be seen from the illustration slides within an upright iron frame surmounting the four rests on castors. When not required as a bed table the wooden slab can be reversed so as to bring the iron support to a more central position under the table, thus giving greater stability. The table certainly possesses advantages, but is not so easily adjusted as is desirable. Unless very great care is taken the iron arm which slides within the upright frame is liable to slip while the side hand screw is being turned, and descend to the lowest point with a clatter which would not be at all beneficial to an invalid suffering or recovering from a nervous complaint. The top of the table measures 1 ft. 6 in. by 3 ft., and can be adjusted between the maximum and minimum heights of 3 and 2 ft. It is sold by Messrs. Millard Bros., 123, Houndsditch, London—price, £1 10s.

THE WILLARD BELL TRUSS.

THIS truss consists of an oval pad, which fits over the external abdominal ring and the inguinal canal; this pad is firmly attached to a stout piece of nickeled steel wire, which passes upwards and outwards above the iliac crest, and, curving backwards, is attached to a broad pad shaped something like the letter W; this is intended to fit over the sacrum and the sacro-iliac articulation on each side. From the termination of the wire at this pad a band passes round the hip of the unaffected side and is attached to a button on the hernia pad. In use we have found that the sacral pad fits very comfortably and the whole truss is light and elegant and keeps back the hernia very satisfactorily. In the specimen submitted to us the force of the wire spring was a little greater than was necessary to retain the hernia, but probably the springs are made of different strengths. We consider the truss a useful and comfortable modification of the usual form. It is made by the Accrington Surgical Appliances Company, Limited, Dale-street Works, Accrington.

THE LANCET.

LONDON: SATURDAY, JANUARY 30, 1897.

THE SANITARY STATE OF THE ARMY IN INDIA.

AS the readers of THE LANCET well know, we have always regarded the policy and action of the so-called "purists" and opponents of the Contagious Diseases Acts as highly mischievous and opposed to the interests alike of public health, public decency, and, we may add, morality. The condition of the British Army in India, as set forth in the *Times* of the 22nd instant, shows where that policy has landed us in that country. Briefly stated, the medical history of the army in respect of these diseases is as follows. From the time when the lock hospitals were closed, all restrictive measures have been gradually surrendered. The results obtained even before that date, however, showed that the system and machinery, as then applied, had proved inadequate to cope with the evil; but if these measures fell far short of accomplishing what they have effected on the Continent, and what had been anticipated from them, we see, now that all restrictive barriers have been taken away and been replaced by a system of free-trade in prostitution, that they nevertheless did impose some check on the flood of disease which has since taken place. The number of admissions—not the number of men, for the same individual may be admitted once or several times—for this class of disease has been steadily rising during the last few years from over 400 per 1000 until it has now reached considerably over 500 per 1000. Nor does the extent of the evil end here, for, according to a very able and vigorously-written article in the *Pioneer*, which the correspondent of the *Times* deemed of sufficient importance to telegraph home, not only has venereal disease been augmented in quantity, but it has acquired such a degree of virulence as to quality that numbers of soldiers have been invalided from India and landed at Netley in a truly terrible and pitiable condition. Would it not be well, by the way, if some of the leaders of the purist party obtained permission to visit these object lessons and see for themselves the practical results of their agitation?

The *Pioneer* may well institute a comparison between the plague at Bombay and the results of this scourge, one being a rare and temporary, the other a perennial and persistent evil, which yearly consigns hundreds of our young and inexperienced soldiers to the grave by loathsome paths of preceding suffering and illness. In the case of the plague we strive to do everything in our power to stamp out and limit the ravages of the contagion; in the other we do nothing of the kind, but all attempts in this direction are branded as the licensing of vice! We must look the facts in the face. Nature has implanted in every man, in common with the lower animals, an appetite so strong that it is hopeless to suppose we can successfully war against it. Deplore it as we may, it is nevertheless a fact conterminous with the history of the race itself that prostitution has existed from the earliest to the present times. No one would willingly allow people to wander about a powder magazine with a lighted torch or pipe. Not to prohibit them from doing so would be regarded as criminal folly; but we must take no steps to prohibit a diseased woman from pursuing her trade in the midst of the highly inflammable material of a short service army! To do so is to interfere with the liberty of the subject and to legalise vice forsooth! We take every precaution to safeguard people from all other infectious diseases, but none must be taken in regard to that kind of infection which does not simply end with the individual attacked, but may be, and often is, conveyed to other and innocent persons and even to the unborn. It is impossible that the whole army should be married at the ages at which men enlist and serve as soldiers. To do so would be tantamount to having no army at all. And we all know, moreover, what it means to allow every young man to marry regardless of his being able to maintain a wife and family; it means misery, suffering, and early death.

What, then, is to be done? It seems to us that we need somebody with the courage of his opinions to grapple with this question. Before we fold our hands and confess our inability to do anything let a full and impartial inquiry be instituted in the first place so as to ascertain the facts; and, in the second, let it be seen whether some method of dealing with the subject cannot be devised and put in force in real earnest. It may be found to be no good merely returning to the old Indian system as it was carried out; if so, let a new and better one be substituted for it. We have for our guidance, at any rate, the results that have been obtained in Continental armies, where restrictive systems are pursued, and the amount of these diseases has been thereby reduced to insignificant figures, which are in striking contrast with the ratios of our own army in this respect. No doubt the difficulties in a country like India are very great, but we cannot regard them as insuperable. It must not be forgotten that prostitution in India is a question of caste, and that if any help is to be given to the "unfortunates" of India it can be done by the aid of legislation and through the instrumentality of a cantonment magistrate in protecting them against incurring debts which bind them like slaves to continue their career. We have had experience of trying to fortify our young soldiers against temptation, and we have tried to provide for unfortunate women when diseased by a system of voluntary hospitals, of which they do not care to avail themselves, and the result has been that things have gone from bad to worse. Is it not time to deal with humanity as it exists, and no longer to proceed on the impracticable lines of a false sentimentality in dealing with one of the commonest and certainly gravest and most persistent forms of contagious disease with which we are acquainted? Having vainly tried to do all in our power to conduce to habits of continence, we may surely now, with a clear conscience, have recourse to other and repressive measures and endeavour to protect our young soldiers against the results of temptations which they seem to be practically powerless to resist. If we may judge by results, too, the application of restrictive legislation in regard to prostitution is attended with moral and social advantages: moral in that it checks many giddy, thoughtless girls at the very outset of their

Hosted by Google

downward grade by the fear of discovery, and secures to the diseased prostitutes rest, food, and treatment in institutions where they will probably meet with more sympathetic kindness and chances of reclamation than they have ever had before. As regards the social effect of such legislation there can be no doubt that it effected, if it did nothing else, a great change for the better in the decorum and decency of those seaport towns to which it was applied. The whole question seems to us to stand in urgent need of further inquiry and of serious consideration.

THE question of quarantine detentions of shipping and of persons is certain to become an acute one in connexion with the proposed international conference as to plague. There are certain nations who, for the purposes of disease prevention, subordinate everything to the one idea of quarantine; and if, by the aid of vast expenditure and of a proper sanitary organisation, such detentions have been shown to be quite unnecessary in certain countries, the generality of nations urge that, with a view to what they term the advantages of an international agreement, the countries that have fitted themselves to cope with foreign diseases on modern scientific lines ought to sacrifice themselves in the interests of those nations whose sanitary administration has been one of more or less complete neglect.

This is briefly the present position of Great Britain in relation to many other States. Our Government has dispensed with all quarantine restrictions as regards cholera, and the knowledge of this has during the past generation acted as a stimulus to our sanitary authorities so to prepare their districts in advance that they shall be able, with a reasonable chance of success, to control foreign disease imported into their midst. This action has been of untold benefit in the prevention of disease and in the saving of life. At the Paris Conference England was asked to share in imposing quarantine, under the disguise of the new-fangled name "observation," in the Persian Gulf; she declined, and now we hear that we alone are responsible for all the evils that may happen in connexion with plague, with which disease, by-the-bye, the proposed quarantine detentions in the Persian Gulf had nothing whatever to do. Last year we took a further step in advance. We got rid even of the form of quarantine as regards plague and yellow fever in the British Isles, and the Local Government Board issued an order from which it is perfectly clear that they intend to deal with plague without resort to quarantine detentions. But directly we enter into any international conference we shall find that the majority of the European nations will demand quarantine, either openly or in disguise; and if we answer that we have decided that in this country we decline to detain healthy people in quarantine on a mere hypothesis that perhaps they may be incubating some disease or other, then we shall be told that we are breaking down all chance of an international agreement and that we, who are spending millions a year in the promotion of public health, have no other idea than the sordid one of securing our commerce. And, if we may judge by the past, the next step will be to accuse us of wanting to introduce disease into the basin of the Mediterranean and thus to infect Europe. Surely the time has come for us to answer that, if uniformity is wanted, there is such a thing as levelling up as well as levelling down, and the mark which is again set before our eyes, as one to be specially aimed at, is distinctly on a lower plane. Uniformity and international agreement are all very well, but the sacrifice that they involve may be a worse evil than a failure to agree. Accusations of the sort referred to are already being bandied about by experts who ought to know better, even if they do not; and it is under the ban of these accusations that we are asked to confer with other nations, some of whom have shown by their past attitude that they hardly care the proverbial "two straws" for the health of the communities for which they are responsible. It is, indeed, only when some panic prevails concerning a disease to which they are not accustomed that they suddenly try to make it appear that they are desirous, in the interests of all nations, to take a share in the control of disease. But that control is nearly always of the same sort—namely, one based on quarantine, which costs them but little, if, indeed, it does not put money into their pockets, and which only inconveniences others.

This, we believe, is in the main a correct and unvarnished story of the attitude likely to be adopted by the majority of the nations whose votes will count at an international conference; and it is a state of affairs that cannot fail to present difficulties to a country which has been endeavouring for nearly half a century to render antiquated and retrograde action unnecessary. So far as our own ports are concerned, medical inspectors of the Local Government Board are already at work and are doing what they can to prepare them better to meet any emergency which may arise; and, so far as India is concerned, we are glad to learn that the Government have felt themselves able to prohibit the departure of pilgrims for Mecca from either Bombay or Karachi. But, as regards plague, land routes are infinitely more dangerous than sea routes. Pilgrims going by sea are daily under such medical observation that detection of plague would be a comparatively simple matter; by land they may here and there have to run the gauntlet of a sanitary cordon, the passing of which in Eastern lands is, as a rule, a matter of money, but minor cases of the disease are very likely to pass unnoticed. We shall, however, doubtless find that, as hitherto, attention will be essentially concentrated on shipping, just as it was at the Venice Convention, even when cholera was slowly but surely advancing along the old land routes in the direction of Europe. In fact, a lock and key at Suez have charms for many who try to forget that long before the Suez Canal was in existence plague and cholera made far worse inroads into Europe than can ever be possible through the agency of traffic by sea, which is both limited in amount and is always carried out under conditions that make it the least dangerous method for the diffusion of infection.

A CASE of somewhat painful interest was tried last week at the Carnarvonshire assizes by Mr. Justice GRANTHAM which illustrates in more ways than one the difficulties of medical practice and the damage which may be inflicted on reputations by hasty and ill-considered statements. It was

Hosted by Google

an action brought by Mr. DEW, a solicitor of Bangor, against Dr. GREY EDWARDS, for many years the trusted medical adviser to the plaintiff, to recover the expenses incurred by the latter by the illness of two of his children attributed to defendant's neglect in enforcing suitable precautions from contagion on the occasion of the fatal illness of another child which occurred just previously to their attacks. It was contended that Dr. EDWARDS had failed to recognise the first case as one of diphtheria, the disease from which the other children subsequently suffered. The hearing of the action occupied the Court for three days, and resulted in judgment being given for the defendant with costs. We can only give a brief outline of the salient features of the case, which, after all, amounted simply to the imputation of mistaken diagnosis and laxity in the adoption of precautionary measures on the part of the defendant.

As presented by the plaintiff, it was averred that Dr. EDWARDS, who was called in to the child STANLEY DEW, six years of age, on Oct. 5th, 1895, did not take a serious view of his condition, and more than once declared that there was no risk of contagion. The child had been sent home from a visit at a relative's house suffering from sore-throat. No membrane could be seen on the throat, but there was a small ulcer on the tonsil. On Dr. EDWARDS'S advice he was removed to a separate room, and not improving a trained nurse was called in. The condition of the throat grew worse, much sloughing took place, glandular swelling and nasal discharge ensued, and death occurred rather suddenly on Oct. 12th. The case was certified as one of "malignant sore-throat," but the bereaved parents in their distress seem to have been only too ready to attribute their loss to other causes, and their surmises were strengthened by what the judge rightly characterised as two unfortunate and hasty statements. When the child was in a critical state Mr. DEW wished for a second opinion, and sent for Dr. WILLIAMS of Holyhead. Before the latter arrived the child died, and after hearing Mr. DEW'S account Dr. WILLIAMS said that the case must have been one of diphtheria. The other incident arose out of a conversation which the plaintiff had some time subsequently with Mr. LLOYD of Bangor, when that gentleman said that he had been told by Dr. EDWARDS that the case was one of diphtheria and that antitoxin had been used. It was clearly shown that Mr. LLOYD had confused this case with the others which subsequently occurred, but Mr. DEW, believing this statement, came to the conclusion that antitoxin had been injected by Mr. FARLEY, who attended for Dr. EDWARDS on the night of Oct. 11th. He called on Mr. FARLEY to question him on the matter, but that gentleman declined to give him any information; nor was the plaintiff any more successful in his inquiry on the same subject addressed to the nurse. It was, indeed, a singular inference to have drawn, that Dr. EDWARDS, who had throughout seen nothing to justify a diagnosis of diphtheria, should have resorted to this line of treatment; but every allowance must be made for one who had been bereaved of his child and in whose mind suspicion had been aroused and allowed to grow. As a matter of fact, there was no foundation at all for this statement. Mr. FARLEY, who is the house surgeon at the Carnarvonshire and Anglesey Infirmary, attended at Dr. EDWARDS'S request to syringe the nostrils, which had become blocked by discharge. In his evidence Mr. FARLEY said he saw no membrane, and concurred with Dr. EDWARDS that the case was one of "malignant sore-throat."

Mr. DEW, unfortunately, having once had his confidence shaken, was all the more prepared to attribute the attacks of diphtheria from which his infant and two other children as well as a maid-servant suffered, to infection from the case of STANLEY. He appears to have read works on diphtheria, and his view as to the nature of the case was supported by Mr. LENNOX BROWNE, presumably one of the authorities consulted. As regards Mr. LENNOX BROWNE'S evidence, we need only say this, that it was unfortunately based upon his interpretation of the symptoms as detailed by Mr. DEW himself; and without in any way disputing the fact that cases of malignant diphtheria run a course not dissimilar from that here presented, it must be remembered that Mr. LENNOX BROWNE had no opportunity of personally observing the clinical features of the case. His evidence, therefore, is of no more and no less value than the rebutting expert evidence given by Dr. LLOYD ROBERTS and Dr. ASHBY on behalf of the defendant, both of whom acknowledged that gangrenous inflammation of the throat of a non-diphtheritic nature does occur—and occur, too, under similar insanitary conditions as those which often dispose to true diphtheria. The evidence given by Dr. EDWARDS himself was plain and straightforward and his account of the case perfectly coherent and comprehensible. He had no grounds for believing that the case was one of diphtheria, although, as may happen to any practitioner, even the most experienced, the possibility of such being the nature of the malady became more apparent when others of the household sickened with unmistakeable signs of the disease. Nevertheless, although he could not regard the case as of this specific nature, he certainly did take all reasonable precautions to prevent contagion. That he did not recognise the gravity of the case at first is not to be wondered at; but even when it assumed a more serious aspect he was only carrying out the wife's injunction not to say too much to depress her husband. It is impossible not to feel great sympathy with the parents in the trouble which befell them; but this sympathy is in great measure neutralised by the action taken by Mr. DEW, who has suffered his anxieties and distress to master him to such an extent as to destroy confidence in an old friend and medical adviser, to create suspicion of his actions, and impute to him serious negligence. Happily for all parties, the case has ended as it only could end, and we trust that Mr. Justice GRANTHAM'S sensible and judicious remarks may bear good fruit.

WIGAN MEDICAL SOCIETY.—A meeting of the above society was held on Jan. 21st, 1897, the President, Mr. C. R. Graham, in the chair. Mr. J. Collier read a paper on Astragalectomy, with Erasion for Pulpy Ankle-joint. The paper, an able and interesting one, with original suggestions, was listened to with much attention. A discussion followed in which the following members took part:—The President, Mr. Monks, Dr. Blair, Mr. Cooke, and Mr. Mitchell Roocroft.

"Ne quid nimis."

THE QUESTION OF A CENTRAL HOSPITAL BOARD FOR LONDON.

THE meeting held on Monday at the United Service Institution for promoting the formation of a central hospital board was a very successful one—indeed, it would be difficult to exaggerate its importance. The fulness of the attendance and the remarkably representative character of the speakers and of the meeting itself were ample proof of the deep hold that this subject is taking of the mind of the public or of that section of the public which in the long run affects public opinion. The representation of the profession was unusually good, consisting, not only of well-recognised exponents of the grievances of medical practitioners but also of a fair number of the members of the medical staffs of the various hospitals. No doubt it was largely a Charity Organisation meeting, and in its very organisation showed the faculty of that society; but the fair field given to opponents and the moderation of the speeches combined to show how serious was the subject and how general is the conviction that the time has come for dealing seriously with it. To the chairman (Lord Stamford) is due much of the credit of the meeting. His own speech and his excellent temper and readiness in preserving order and discipline were most useful in contributing to good discussion and in eliciting a clear vote in favour of a central board by a majority of 121 to 12. But the speech of the occasion was that of Sir William Broadbent. The painful feeling that has possessed many medical men of late in connexion with this subject is one of anxiety lest the profession should be fatally divided upon it, and lest its members who constitute the staffs by which the work of hospital charity is done should prove indifferent to the wide abuse which has grown up like a canker in the monstrous development of the out-patient department. The speech of Sir William Broadbent will do much to allay this anxiety, and the presence of many other consultants at the meeting together with the letters read from Sir James Paget, Sir Edward Sieveking, Sir James Crichton Browne, Dr. Lauder Brunton, and others will have the same effect. Sir William Broadbent's position in the profession and in public favour might have supplied him with many arguments for adopting a Gallio-like attitude with respect to this movement. But he has well judged in speaking out clearly in sympathy with the bulk of the profession. In so doing he may save both the hospitals and the profession. He made his points well and in such temperate terms as to defy serious opposition. He showed that it was notorious that patients went to the hospitals for whom hospitals were never meant; that was a matter which concerned both the public and the profession—primarily the general practitioner, whose fair field of work was invaded, and next the physicians and surgeons of the hospitals, whose energy was wasted and whose time was misapplied. It was bad for the poor, for they were detained and received less attention than their cases required. Another great evil was the want of coördination of hospitals, each playing for its own hand and engaging in a vicious competition to show mere numbers. The quality of Sir William Broadbent's speech was well shown in the judgment with which he dealt with the question of special hospitals and the error of general hospitals in not soon enough recognising the need for some specialisation of work within their own walls. He disclaimed strongly all hostility to hospitals and any desire to abolish a proper and healthy rivalry in doing best for the patients and in seeing that the patients were worthy. He did great service to hospital authorities in supposing that they would come to recognise the necessity of some sort of central board and of coöperating harmoniously with it. A very important part of his speech was that in which he alluded with much hope to rumours of the Royal favour with which in this auspicious year schemes for relieving and benefiting the hospitals are regarded by Her Majesty the Queen and His Royal Highness the Prince of Wales. No more Royal thing could be done than the use in such a cause of the Royal favour. The fund so raised would have to be entrusted to a board which by its very functions would be entitled to a certain supervision of the institutions so favoured. We are heartily in accord with the wishes of Sir William Broadbent in this matter. We see nothing in the temperate and reasonable opposition of the speakers at the meeting to make us despair of the speedy success of this movement. Mr. Myers, the Rev. Dr. Wace, and Mr. Keetley were all well within reason in objecting to details in the specific motion proposed by Sir William Broadbent. But their objections and those of Dr. Lauder Brunton were well met by the assurance that nothing will be done without giving full consideration to the managers of hospitals and dispensaries, whose services in the cause of humanity must always be recognised. The one thing that may spoil this movement is division in the medical profession. It is the last profession that can take any exception to hospitals which keep within their functions, and if its various sections agree on reasonable lines the reform will be one of the achievements of this notable year. Let it be remembered that no cut-and-dried scheme is proposed and that on any Central Board that is likely to be formed the hospitals themselves will be—nay, must be—fully represented.

THE PLAGUE.

IT has been computed that the total number of victims to the plague at Bombay during the four months that it has prevailed in that city did not exceed the number that perished in London in about the same number of days in 1665. The official returns in either case did not probably accurately represent the actual number of deaths attributable to that disease. We know that in the great plague of London it was the opinion of Defoe that they did not do so and no doubt he was correct, as there were no reliable statistics in 1665. In connexion with this subject it may be interesting at the present time to refer to an occurrence which took place in 1876. In that year it was proposed to carry out some military works in one of our large garrisons abroad which would necessitate the disturbance of the remains of those who had fallen victims to the plague which had prevailed there in 1665. The local board of health took alarm and strongly recommended that certain stringent quarantine procedures should be adopted in regard to the workmen engaged, lest the plague of over two hundred years ago should be resurrected and possibly communicated to them from the ground and any remaining fragments of bone. As the steps proposed to be taken would occasion considerable expense and inconvenience and possible danger from the close proximity of a powder magazine the matter was referred to this country for an opinion as to whether the assumption rested upon any basis of fact. Of course, if it could be shown that there was any instance on record of plague having broken out from such a disturbance of the soil after the lapse of two centuries the precautionary quarantine measures might possibly be justifiable. This led to inquiry, with the result that might have been anticipated. We know historically that in the Great Plague of London upwards of 100,000 persons died from the disease and were not only buried in plague pits near the present site of Golden-square, at Goswell-street, Finsbury,

Hosted by Google

Tothill Fields, Cripplegate, and elsewhere, but in every churchyard of the City and surrounding parishes. These continued to be afterwards used for all classes of interments, with the consequent continuous disturbance of the soil containing plague remains until the grounds were finally closed—more than a quarter of a century ago. Some of the churchyards were entirely emptied of remains in order to fit the ground for building purposes without incurring the slightest degree of risk against which the precautionary safeguards were proposed to be directed. Moreover, sewers, gas-pipes, water-pipes, and telegraph wires must have been laid and frequently repaired in situations where plague patients had been interred more than two centuries ago. The following facts were elicited in the inquiry, and they show how large were the plague interments in some of the metropolitan burial grounds:—Ninety-seven parishes within the walls, 9887; St. Andrew's, Holborn, 3103; St. Giles, Cripplegate, 4838; St. Botolph, Aldgate, 4051; St. Olave and St. Saviours, 6231; St. Giles-in-the-Fields, 3216; St. Martin-in-the-Fields, 2883; St. Mary's, Whitechapel, 3853; St. Margaret's, Westminster, 3472; and St. Dunstan's, Stepney, 6583. It is needless to add that in the face of this large experience, and in the absence of any evidence of plague having ever been reproduced by disturbances of ground 200 years after interment, the conclusion arrived at was that no other precautions were necessary beyond such as would be taken in the removal of the soil and remains of any cemetery at the station in question.

VISIT OF LORD LISTER TO BELFAST.

ONE of the most interesting events in connexion with the jubilee of Queen's College, Belfast, was the visit of Lord Lister, who was the guest of the President of the Ulster Medical Society, Professor J. Symington, who in former years was one of his house surgeons. On arriving at the College on the afternoon of Tuesday, Jan. 19th, Lord Lister received a tremendous ovation from the students, who unyoked the horses from the carriage and drew him in triumph to the new Union Buildings. In the evening the President of the Ulster Medical Society invited a large number of medical men, students, and leading citizens of Belfast to a symposium in honour of Lord Lister, which was held in the Medical Museum. An excellent programme of music was provided, and on rising to respond to the toast of his health proposed by Professor Symington, Lord Lister was received with the greatest enthusiasm. He said he had often heard of Irish hospitality and Irish enthusiasm, but never experienced them as he had done that evening. Having thanked all those present for the very cordial manner in which they had greeted him Lord Lister concluded by proposing the health of Professor Symington. On Wednesday forenoon (Jan. 20th) Lord Lister delivered a most interesting address in the library of Queen's College in connexion with the opening of the new laboratories. There was a very large attendence of medical men and students. President Hamilton having taken the chair, an address was presented to Lord Lister from the North of Ireland branch of the British Medical Association and the Ulster Medical Society, for which Lord Lister returned his warmest thanks, and then, on the invitation of the President, gave an extremely brilliant address on the great advantage the establishment of the new laboratories in physiology and pathology (opened the previous day by the Lord-Lieutenant) would be to the north of Ireland. He showed how both the general practitioners would be helped in their diagnosis of such diseases as diphtheria, &c., by such an institute, while it would be an immense help in the training of the students in their education for the medical profession. The bacteriological department would be of peculiar value in convincing the student of the reality of the microscopic foes with which he had to deal so largely—the microbes which were the cause of such a large number of human diseases. The making of a culture experiment, which needed so much care, was in itself a great source of education. He spoke of the absurdity of the objections of the antivivisectionists, and showed how peculiarly humane a man Pasteur was. He gave an interesting account of the investigations as to the microbe of the plague, which he had learned recently on a visit to the Institut Pasteur, and of M. Yersin's serum treatment of the plague. He showed how such a disease as the plague might be easily carried from Bombay, where it was already prevalent, in ships. Rats were liable to contract it, and a rat making its escape from a ship coming from Bombay—say, to the Thames or to Belfast Lough—might carry the plague ashore and entering any of their slums might affect human beings with this dreadful disease. Hence the necessity of having means at hand for combating such a malady. In conclusion, Lord Lister referred to the Royal Hospital, which he had visited that day, and which was altogether inadequate to the requirements of a great and growing city like Belfast; but he rejoiced that better things were in store for them and that within six weeks of the initiation of the movement for the new hospital more than half the necessary sum had been raised. He thought, therefore, whichever way he looked at this jubilee, that Queen's College, Belfast, more particularly with regard to its medical school, was entering upon a new era of prosperity, and he had felt it a great privilege to take part in their celebration. He hoped that the time was not far distant when the great northern metropolis would have its own University—a true teaching, graduating University—on the same lines as most of the German and the Scotch universities. At the conclusion of Lord Lister's lecture, which was most cordially received, Professor Mallet Purser (Dublin) and Professor Coats (Glasgow) addressed the meeting, and a most enthusiastic vote of thanks was accorded to Lord Lister. In the afternoon a large number of the citizens of Belfast and of the medical profession were invited to meet Lord and Lady Kelvin and Lord Lister at the Belfast Hospital for Sick Children. To the great regret of the graduates Lord Lister at the last moment was unable to be present at the banquet, having been commanded to appear at Marlborough House.

KITCHEN BOILER EXPLOSIONS: FOREWARNED, FOREARMED.

WE are experiencing just now a sharp "snap" of cold weather which calls to mind the severe frost of just two years ago. Nothing, of course, is more uncertain than English weather, but it is a curious, though perhaps not a very reassuring, fact that the present spell of cold weather was preceded by just the same remarkable series of phenomena which characterised the commencement of the severe frost in the early weeks of January, 1895. Thus, as on that occasion, we experienced on Monday a very wild and stormy day, with snow, hail, and rain, accompanied in some parts of the country by thunderstorms. Then a slight thaw set in, which, however, soon made way for continuous frost. This is precisely what occurred in January, 1895, previously to the continuance of a very exceptional period of severe frost, and it behoves us to be on our guard against the dangers which a prolonged frost may bring in its train. One of the most serious of these, as experience has shown, is in connexion with the possibility of kitchen boiler explosions, arising from the freezing of water in the supply-pipes. Already we learn that some inconvenience has been experienced from the freezing of water in the cisterns, but happily the frost has not lasted long enough as yet, or has not been sufficiently severe, to lead to more serious

Hosted by Google

possibilities. But it may continue; and disaster may be prevented with a little watchful care and attention. As is now well known, kitchen boiler explosions may be prevented by means of a good safety valve. Those who have not this provision should bear in mind that the fire should never be allowed to go out. If the fire is allowed to go out it should be ascertained before lighting it again that water flows from the hot-water taps, and after the fire is lighted it should be kept low for a time until the pipes and the water flowing from the taps give evidence of gradual heating and of circulation being established. The knowledge of these simple facts, if acted upon, would prevent many a serious occurrence and stop the record of disasters which unfortunately characterised the severe frost of two winters ago.

THE CAUSATION OF SEX.

THE determining factor in sex has always been the subject of controversy, but up to the present time, although numerous theories have been propounded, none can be deemed satisfactory, and the causation of sex is still as much shrouded in mystery as is biogenesis. Perhaps one reason why so little progress has been made in the elucidation of this profound problem is the fact that there are so few opportunities of ascertaining reliable facts relating to the human subject in this connexion. Be this as it may, there can be no doubt that experiments on animals with a view to clearing away the mist with which this question is obscured would greatly add to our knowledge of the subject, and if the controversy which is taking place in the columns of our contemporary, the *Stock-keeper*, should have this effect not a little good may result. The theories which up to the present have been propounded are well known to readers of THE LANCET, in the columns of which several attempts have been made to thresh out the subject; but a letter from Mr. J. F. Chambers in the issue of the *Stock-keeper* of Jan. 8th, in which he ably propounds what may be called the katabolic and anabolic theory, will be read with interest. He says the fœtus passes through three cycles: (1) sexless; (2) hermaphrodite or bisexual; and (3) unisexual; and argues that at the second stage the "breeder may step in and enjoin nature to proceed after his wishes." The practical results of breeders' experiments, however, will be more valuable than any number of theories.

THE LAW WITH REGARD TO VERMIN.

BLOOMSBURY has an unenviable reputation based on an alliteration between the name of the district and the name of the insects which are said to abound in the houses. It would seem that the law can afford no help to those who would do away with this unpleasant characteristic. At the Bloomsbury county court a claim was made against Mr. Phillips of Ridgmount-gardens for £20 in payment of the first quarter's rent for a flat at York-gate-mansions, Regent's-park. The tenant on occupying these premises found that they were overrun with bugs. On going to town he discovered that six or seven of these *Cimices lectularii* had secreted themselves in the lining of his hat. He had barely reached his office when he received a telegram from his wife asking him to return at once. This he did, and then saw that the rooms were literally swarming with the vermin. A new carpet, which had not yet been used, was in such a condition that it had to be destroyed. Unable to cope with such an invasion Mr. Phillips left the flat and refused to pay the rent, on the ground that it was unfit for habitation. The plaintiff urged that the flat had been habited by the previous tenants for three years, that there had never been any complaint with regard to vermin, and that in renting the flat the new tenant had not asked if it was habitable. This latter is certainly a strange plea, for it should go without saying that a dwelling offered for hire is fit for habitation. The county court magistrate held, however, that there was no proof of implied warranty that the flat was free from vermin, and could not accept the theory that the presence of bugs proved a dwelling to be unhealthy. The verdict was therefore given for the plaintiff. The question arises from this case whether a dwelling swarming with bugs may be considered unhealthy. We cannot but think that when a house is overrun by such vermin it is a proof of filth and that dirt is unhealthy. Also, it is only natural to look upon a dwelling as a place of rest where the inhabitants will be able to sleep in comfort. But sleep under the conditions described must have been well-nigh impossible, and there is no denying that the want of sufficient rest is detrimental to health. According to the verdict given it will nevertheless be necessary to insert two special clauses in every lease: the first shall stipulate that the house must be habitable and the second that it must be free from vermin. Perhaps landlords will then require a third clause to the effect that a house let free from vermin shall be kept free from vermin by the tenants. Agreements on these lines would be of considerable benefit to all concerned. They would enforce cleanliness upon the tenants and this would be conducive to the preservation of public health. In the meanwhile it does not seem fair that Mr. Phillips should have had to suffer for the neglect of others.

A SIMPLE METHOD OF WATER ANALYSIS [1]

MEDICAL officers of health will welcome a method of water analysis which is simple in detail and sufficiently accurate to enable a definite opinion to be given as to the character of a water for drinking purposes. Of course, in these days of sanitary progress a medical officer of health cannot be said to be qualified for his duties unless he possesses a knowledge of water analysis. He should know how the analysis is conducted and how to place a fair interpretation upon the results. To do this he must be provided with a small laboratory equipped with the necessary apparatus and re-agents set apart for the special purpose. The chemical examination of water-supplies, useful as it frequently proves to be, is often neglected because of the somewhat complicated nature of the apparatus it requires and the time which a fairly complete analysis would entail; and it is within the experience of most medical officers that in general the advice to submit a sample to an analyst for examination is unheeded, so that unless the medical officer undertakes the investigation himself it is not done at all. In the interests of the public health it is very desirable that its guardians should be possessed of some easy means of arriving at the nature and quality of a given water-supply for themselves, and Dr. Thresh, the medical officer of health for the county of Essex, has devised a simple method to meet this serious deficiency. The re-agents employed are in the form of soloids, each soloid required to complete a given reaction representing a given quantity of the constituent sought. To give an example. When it is required to estimate the chlorides in a water; 70 c.c. are placed in a glass cylinder and a soloid of chromate of potash (indicator) added which is easily crushed by the end of a glass rod, so that the contents readily dissolve when the water is stirred. This done a soloid of nitrate of silver is added in the same way. If no red colouration is produced more soloids are added until the liquid remains red when well

[1] A Simple Method of Water Analysis. By John C. Thresh, M.D. Vict., D.Sc. Lond., D.P.H. Camb. London: J. and A. Churchill, 7, Great Malborough-street. 1897. Price 2s. 6d. (We may add that a special water analysis case, price 2 guineas, containing the soloids and apparatus required in this method, is supplied by Messrs. Burroughs, Wellcome, and Co., Snow-hill-buildings, E.C.)

Hosted by Google

mixed. This indicates the end of the reaction, and each soloid used corresponds to two grains of chlorine per gallon. Further examinations—in regard, for instance, to the quantity of nitrites, nitrates, free ammonia, and even hardness—are conducted in the same way, while similarly the presence of objectionable metals can be detected and a measure of the organic impurity of the water made, judging by the amount of oxygen absorbed. This is done by adding to 70 c.c. of the water, until a faint and permanent pink appears, soloids of permanganate of potassium, each of which corresponds to 0·10 grain of oxygen absorbed by the organic matter in one gallon of water. A certain amount of care and discretion, of course, must be exercised in certain cases, but, as Dr. Thresh has satisfactorily shown, this method gives results which compare very favourably with the ordinary methods of analysis, which occupy much more time and involve the use of more complex apparatus. The introduction of this simple and approximately accurate series of processes should prove a valuable aid in the sanitary service.

LONDON CHILDREN AND DEATHS BY FIRE.

AT an inquest held upon the 25th inst. concerning the death of a child, aged seven years, from injuries received by her pinafore catching fire, Mr. Wynne E. Baxter mentioned that he considered it of great importance that children should be taught what to do under such circumstances—namely, to lie down on the floor and roll over and over. He had communicated with the London School Board and they had agreed that instruction should be given on the matter. It is not always that we have been able to praise the Board, but upon this occasion we do so most heartily. If they would only eliminate some of the unnecessary subjects they teach and substitute a few more of these practical lessons it would be better. It used to be—and may be still for all we know—the practice at a well-known school founded for deserving lads of poor condition and not supported out of the rates to set at the end of every "half" a "common sense paper." Why should not the Board do this? It would be an admirable exercise for the children. We congratulate Mr. Wynne Baxter on his successful procedure.

TABES DORSALIS AND MENTAL DISEASE.

IN the last number of the *Journal of Mental Science* Dr. Macdonald and Dr. Davidson of the Dorset County Asylum record a case of Tabes Dorsalis associated with mental change not characteristic of general paralysis. The patient was a man, aged thirty-nine years, who was found wandering, and on admission to the asylum it was noticed that there was inequality of pupils, loss of reaction to light, internal strabismus of the left eye, and loss of knee-jerk, but no fibrillary tremors. He spoke in a slow, drawling fashion, was confused as to dates, &c., depressed as to his disease, and irritable and emotional. His symptoms during the next few months did not vary much. He was subject to attacks of great irritability, followed by emotional instability and mental confusion. Three months after his admission he was seized with epileptiform convulsions affecting one side, and in these he died after about twelve hours. There were found to be localised areas of atrophy among the convolutions of both hemispheres, the pia mater was thickened, and there was excess of cerebro-spinal fluid, but no change in the vessels. In the spinal cord, sections of which were made and examined by the microscope, there was found to be extensive posterior sclerosis with thickening of the arterioles. The case had been certified as one of general paralysis with tabes dorsalis, but the writers point out that there is to their minds no justification for labeling such a case as general paralysis, as the characteristic clinical symptoms, especially the tremors, were absent and the post-mortem findings were not such as to make it certain that they were such as are met with in general paralysis. Their real object is to point out the fact admitted by many writers, but not generally recognised, that the mental disturbance associated with some cases of tabes dorsalis is not that of general paralysis. No doubt the psychical condition usually occurring with tabes is general paralysis, and in such cases we must suppose that a degenerative process is at work in the cord and also in the cortex cerebri. In this case also, apparently, there were changes in the cerebrum as well as in the cord; but the writers are of opinion that these, even taken with the clinical symptoms, especially the epileptiform convulsions, are not sufficient to justify a diagnosis of general paralysis.

EXTRAORDINARY VERDICT OF A JURY.

THE *Birmingham Post* records an account of an extraordinary verdict of a jury at Walsall. The case was one in which the Apothecaries' Society prosecuted a man for having illegally acted as an apothecary in contravention of the Act of 1815. It was proved that the defendant had supplied medicine to some people and no witnesses were called for the defence. His Honour Judge Griffiths then put it to the jury that the defendant had acted illegally and, that that being so, there must be a verdict for the plaintiffs. The jury, however, after a brief consideration found unanimously for the defendant, and after being told by the judge that such a decision was not in accordance with the evidence one of them said that they found the defendant had practised illegally, but there seemed much mystification and haziness about the Act, and therefore they unanimously found for the defendant. His honour thereupon ruled that this was in reality a verdict for the plaintiffs. In this case the jury appear to have thought that because they were not able to understand the Act they were entitled to give a verdict which they knew to be directly against the evidence and the law. Fortunately, however, they were overruled, and the fate of the defendant will serve as another wholesome example to those who practise medicine without the right to do so. Perhaps, if some of the members of the jury had chanced to have been treated by such practitioners they would not have been quite so ready to shield them.

THE LAW AND THE PUERPERAL POOR.

DURING the holding of an inquest at the Mortlake Mortuary on a child who died aged three days, Mr. A. Braxton Hicks elicited some instructive facts as to the state of midwifery among the poor in that district. The father of the child went for a medical man, Dr. R. D. Mackintosh, at two o'clock in the morning. It was admitted that Dr. Mackintosh had not been engaged to attend the case, and on learning that the patient could not pay he declined to attend. The relieving officer refused to give an order for a medical man on the ground that the husband was at work and he was prohibited by rule in such case from giving one. Dr. Mackintosh, on being examined, said that had he understood the case to be one of urgency he would have gone. He then made the remarkable statement that he *had had forty or fifty cases of this sort in a year and had never received a penny for any of them.* This shows a demoralised state of the district as respects this question and may well make medical men stand upon their rights. Another practitioner of the neighbourhood, Dr. Weir, who made a post-mortem examination on the child and found it to weigh 2 lb. 2 oz., was examined. He attributed this state of matters to the introduction of a midwife into the parish by a nurses' association, who found it more profitable to attend tradesmen's families for 10*s.* than the poor for 5*s.* Both practitioners agreed that this system was

Hosted by Google

ruining the profession. The coroner disagreed with the relieving officer and thought that the officer had the power to have given an order in such a case. The husband's wage was 20*s*., and Dr. Weir described the wife as half starved. The coroner agreed with the complaints of the medical men, and the foreman of the jury said he hoped these would take it from the jury that they thought that others were taking away from medical men their professional work. He testified to Dr. Mackintosh's kindness in really urgent cases. The expression of opinion by the jury and the coroner, confirming that of the medical men, should lead the guardians of the neighbourhood to investigate the state of matters in the parish and to give explicit orders to their relieving officers to give medical orders in such cases.

MEDICAL CERTIFICATES AND THE LONDON SCHOOL BOARD.

THE London School Board has at last done something sensible. On Thursday, Jan. 21st, Mr. Whiteley moved, and Mr. Riley seconded, the following motion: "That in cases where the magistrate or justices of the peace is or are dissatisfied with the medical certificate furnished, and in cases where the medical certificate is *prima facie* unsatisfactory (and when the certificate is signed by a registered medical practitioner), the Board's medical officer shall in the first instance communicate with the practitioner giving the certificate, and in the event of such certificate being ultimately acted upon the fee of 2*s*. 6*d*. shall be paid by the board for the confirmation of such certificate, and that so much of the resolution of July 30th, 1896, as prescribes that 'in cases where the magistrate or justices of the peace is or are dissatisfied with the certificate furnished, the system now in operation be continued' be rescinded." This motion was agreed to after a hostile amendment had been negatived. The thanks of the medical profession are due to Mr. Whitely and Mr. Riley for this result. The latter has fought the question of medical certificates for some two years in the face of a bitter opposition and the former has spared himself no trouble to ascertain what the profession really thought upon the matter and was the drafter of the motion which is now passed.

REFUSE DESTRUCTOR AT OLD TRAFFORD.

THE inhabitants of Old Trafford are alarmed at the prospect of having a "destructor" set up in their midst. Though practically, by proximity and density of population, a part of Manchester, Old Trafford is under the government of the District Council of Stretford. From this village, which still retains some traces of rusticity, it is separated by a sparsely populated interval, and the two have but little in common. It is said by the objectors that the matter "has been pushed forward by the representatives from the Stretford end of the township, who have no special interest in Old Trafford," which strongly opposes its being placed "in the most densely populated part of the township and adjoining the already too unhealthy and crowded ward of St. George's, Hulme," which is part of Manchester. The writer of a signed letter in the *Manchester Guardian* suggests a site about half-way between the two on vacant land far from any dwellings, where "it would be neither a nuisance nor injury to anyone." Some time ago the people of Moss Side were threatened with a destructor; but by their action at the election of their district council they compelled the abandonment of the scheme for its erection. The question as to a destructor being or not being necessarily a nuisance always leads to violent controversy, but it is one of fact and should not be made one of sentiment. Some destructors have undoubtedly been defective in design or construction and could not be used without offence. But in some cases "cremation" is the most convenient mode of getting rid of refuse and, if it be so carried out that no gases escape before combustion is complete, there should be no nuisance and no opposition. It ought not to be difficult to ascertain the fact as to whether or not any of the destructors now in use come up to such a standard, but there is so much fear of annoyance from them that facts are too often put in the background and obscured by prejudice. The *Manchester Guardian* thus concludes a leading article on the subject: "But if Old Trafford is forced to accept this destructor its position will be unhappy indeed, what with the odours of the [ship] canal and the fumes from burning refuse."

THE LATE SIR ISAAC PITMAN.

THE system of shorthand known as phonography has proved to be of such utility to the medical profession that, as medical men, we cannot but record our sense of our indebtedness to its inventor, who passed away at his residence at Bath on the morning of Jan. 22nd. The enthusiasm and energy with which he pursued what Dean Alford called "that wretched attempt to destroy all the historic interest of our language which is known by the name of phonetic spelling," were remarkable; but it was in recognition of the usefulness of his other well-loved child, Phonography, that Mr. Pitman received knighthood on the recommendation of Lord Rosebery in 1894.

LONDON POST-GRADUATE COURSE.

THE eighth year (spring term) will commence on Monday, Feb. 15th, and entries may now be made. The facilities afforded to practitioners have proved of great service owing to the practical nature of the instruction. It is hoped that these facilities will soon still further be increased so as to make the teaching continuous and enable medical visitors to find at all times the help they need. Classes are being formed at Blackfriars (Skin), Bethlem (Mind), London Throat Hospital, King's College (Bacteriology), Cleveland-street (General Medicine and Surgery), Parke's Museum (Hygiene), and at the Institute of Preventive Medicine (Clinical Chemistry). Applications should be sent to Dr. Fletcher Little, Secretary, 32, Harley-street, W.

UNQUALIFIED PRACTITIONERS AND PRINCIPALS IN ABSENTIÂ.

ON the 22nd inst., according to the *Globe*, Mr. W. E. Baxter, coroner, held an inquest at the Poplar town-hall respecting the death of Ellen Shayes, widow, aged sixty-nine years, and living with her married daughter, Mrs. Ada Wright. In the course of the inquiry it transpired that Mrs. Wright went for Mr. C. W. Smith of North-street. His assistant attended and prescribed some medicine. The patient becoming worse Mrs. Wright sent "for the doctor again." The assistant would have nothing more to do with the case, and referred them to Mr. H. J. O'Brien. By the time Mr. O'Brien arrived the patient was dead. Mrs. Wright thought the assistant was a qualified man. The assistant, on being examined, said his name was William Pratt Maule; he was a chemist and assistant to Mr. C. W. Smith, who lived at Leyton and attended at Upper North-street "about three times a week." On the day in question Mr. Smith was expected but did not arrive. The assistant said he was asked to see the deceased, having told the messenger that "Dr. Smith" had not arrived. He did not tell them he was not qualified. Mr. Smith's name was on the plate. The coroner and the jury both expressed themselves strongly on such a system. The coroner said there was a great deal of practice in the East-end not according to the best views of the profession. He made another important remark which needs to be much pondered in this age of cheap medicine. "The people who

Hosted by Google

came before him seemed to think more of getting a bottle of medicine than of being told what was the matter with them." The foreman thought this sort of thing should be stopped. The jury returned a verdict of death from natural causes, but added, "We desire the coroner to communicate the facts of the case to the Medical Council." They would have failed in their duty had they not done so. When will this evil cease and medical men recognise that they expose themselves to grave consequences by a system which misleads the poor?

ANTISEPSIS IN THE TREATMENT OF INFANTILE DIARRHŒA.

THE part played by bacteria in the production of the diarrhœa of infants was suspected and practically admitted by many long before the researches of Escherich and others had established this theory of its origin upon a scientific basis. According to the observer just mentioned, the two forms of germ life most active in the production of diarrhœa are the bacterium coli and the bacterium lactis. The influence of the latter will suffice to explain why it happens that a large number of cases of infantile diarrhœa—we might almost have said all such—become amenable to treatment when the usual milk dietary is reduced, or even for a short time discontinued, in favour of one consisting of fresh raw meat juice. The bacterial hypothesis explains also the success which has in a number of cases attended the temporary discontinuance of all nourishment and the substitution in its stead of boiled and subsequently cooled water given frequently in small quantities. This method, which has recently attracted some attention in France (*Journal de Clinique et de Thérapeutique Infantile*, Jan. 14th), is not altogether novel. Its *modus operandi* in cleansing and procuring rest for an overwrought bowel while maintaining blood-pressure by its ready absorption calls for little explanation. Something also remains to be said in favour of the procedure, often successfully employed in the case of dysentery, which obeys the same teaching, and by combining a sedative with an excitant of the liver aims at producing by means of the bile the moderate action of an antiseptic force which is resident in the body itself.

THE LONDON CHILDREN ASYLUM DISTRICT.

WE are to have a new Metropolitan Asylum Board. The enormous development of the Metropolitan Asylums Board for the treatment of infectious disease might well make the authorities hesitate before creating another set of asylums for the separate treatment of certain children under the Poor-law. The cost of the hospitals is great but, nothing daunted, the Local Government Board has drafted an Order for forming the several unions and parishes in the metropolis into a Children Asylum District under the Metropolitan Poor Amendment Act, 1867, and the Metropolitan Poor Amendment Act, 1869. This Order is the outcome of the recommendations of an influential departmental committee which investigated the whole subject of the treatment of children in pauper schools and which was pretty unanimous in its recommendations, but did not carry the concurrence of Sir John Gorst and Mrs. Barnett. The children for whose benefit this new departure is taken are thus specified: (*a*) Children suffering from ophthalmia and other contagious diseases of the eye; (*b*) children suffering from diseases of the skin and scalp; (*c*) children requiring either special treatment during convalescence or the benefit of sea air; (*d*) children who by reason of defect of intellect or physical infirmity cannot properly be trained in association with children in ordinary schools; and (*e*) children who are ordered by two justices or a magistrate to be taken, under the Industrial Schools Act, 1866, to a workhouse or an asylum of the district. The board of management is to be elected by the guardians of the metropolitan parishes. This looks very like the starting-point of five or six brand new separate asylums under special management, and likely to be very costly to the ratepayers. Undoubtedly some special consideration is necessary for children unfortunate enough to be handicapped in the race of life in the ways specified above. But we agree with those who think that it is questionable whether the course adopted by the Local Government Board is the best one. While creating huge asylums for the children it in no way liberates them from the care of the guardians or the Poor-law system, which seems almost in its very nature to breed unhealthinesses of its own. Such evils are not likely to be eradicated without the introduction of more special knowledge and care into the question than are likely to be provided by guardians who have proved themselves bad custodians of the public health. Besides, the policy of multiplying establishments for the concentration of the chronic infections of children is open to very much criticism apart from the financial objections to such a course.

THE DEPARTMENTAL COMMITTEE ON RABIES.

THE *Times* "understands that the Departmental Committee appointed by Mr. Walter Long last year to consider the best means of stamping out rabies has reported in favour of re-establishing the principle of centralised control. It is recommended that this power should be transferred back to the Board of Agriculture, whose duty it would then be, on receiving a notification of an outbreak of rabies, to ascertain the probable limits of infection and to make a muzzling order covering the whole area within those limits. Other suggestions are that every dog shall be required to wear a collar bearing its owner's name and address, together with a distinctive mark showing that it has been duly licensed; that questions of exempting certain dogs, such as sheep-dogs, from taxation shall be decided by the magistrates in petty sessions or some other local body instead of by the Inland Revenue authorities as at present; and that regulations shall be made for ensuring that none but healthy dogs be allowed to enter this country from abroad." The idea of centralising control seems to us to be an excellent one, but we are sincerely sorry for the Board of Agriculture, whose duty it will be to ascertain "the probable limits of infection." How the Board is to do this we cannot quite see. That the persons who are responsible for dogs should be known by means of the said dogs wearing collars with the names and addresses of their owners is also a suggestion we hope to see carried into effect. Hydrophobia is so terrible a disease that preventive measures, no matter how inconvenient to either dog or master, ought to be rigorously carried out; and if those well-meaning but wrong-headed individuals who write to the papers about the cruelty of muzzling orders were only to see a case they would not write the nonsense which they do.

"RETURN" CASES OF SCARLET FEVER.

AT a meeting of the board of the Islington guardians held on the 21st inst. a communication was read from Mr. Dewey, vestry clerk, enclosing a report from Mr. Harris, medical officer of health of Islington, with regard to a visit to the Kingsdown Orphanage to inspect a child, aged ten years, who, it was alleged, had been discharged from St. Ann's Hospital, Tottenham, while in an infected condition. Mr. Harris, in his letter, supported the allegation. He found desquamation still going on. The statements, as reported by Mr. Harris, seem almost incredible. The medical officer of the hospital wanting two wards the day before the patient's discharge fifteen beds were taken down. He said if the patients were not well enough they must be removed to Winchmore-hill. The nurse spent the afternoon in rubbing the hands and feet with pumice stone,

Hosted by Google

and said she would "show the patient up." On the morning of discharge the patient was taken to the bath-room, but there was no hot water, in consequence of which the nurse only bathed her feet and hands. The matron of the orphanage infirmary informed Mr. Harris that when the child returned the hair was full of scurf and there was "life" in it, which was not the case when she left. A similar case was reported to the guardians by Dr. Marshall in a child who, after being in hospital for eight weeks and sent home, was found to be desquamating, and seemed to be the source of a second case seen by Dr. Marshall. The first was desquamating on both hands and one foot. Both of these returned children had moved about with perfect freedom among other children at home, at school, or at the Sunday-school. The dissemination of scarlet fever, still so ubiquitous in spite of isolation hospitals, gives importance to these facts.

THE GOVERNMENT AND FOOD ADULTERATION.

As we announced last week Mr. Kearley gave notice that he would move an amendment to the Address from the Throne regretting that no intention was expressed of promoting legislation in furtherance of the report of the Select Committee on Food Products. This amendment was duly moved and negatived in the House of Commons on Monday last, but not without considerable discussion. This result might safely have been predicted in view of the pressure of national affairs and of the very full programme before the House this session. The subject of food adulteration cannot be considered as one of minor importance, and in some respects it is a matter of regret that the provisions laid down by the committee in their report cannot soon be drafted in the form of a Bill which would make those recommendations (with due amendment of course) law. Although the action of the House in rejecting this amendment will delay an important piece of much needed reform the debate on Monday proved that a decided interest has at length been aroused as to the urgency of reform and, although no definite promise was given that the question would be dealt with this session, yet it was stated that it would be considered at the earliest opportunity. Indeed, according to Mr. T. W. Russell, a draft bill had been already prepared and was being carefully considered at the time by the Local Government Board, who were engaged in removing some of the difficulties which would be met with on a realisation by law of the proposals made by the committee. We have already pointed out that these proposals must receive the greatest possible consideration before they can become law. As Mr. Balfour said, the subject, as was evident from the facts touched upon by those who had taken part in the debate, was one of great difficulty and complexity. It had engaged the attention of a very competent committee for no less than three years of continuous and arduous labour, and its recommendations were of a complicated, and far from being of an uncontroversial, character. While we regret the delay because it is very desirable that the present Acts should be strengthened yet it is obvious that a drastic measure of this kind might lead to disastrous results if unduly hurried through the legislative machine.

AT St. Martin's Town Hall on Friday night last (Jan. 22nd) Mr. Bancroft delighted an enthusiastic audience with his appreciative rendering of Dickens's "Christmas Carol" in aid of the funds of Charing-cross Hospital. Mr. Bancroft will give the same reading on Tuesday afternoon, Feb. 16th, at 3.30 P.M., at Stafford House, St. James's, on behalf of the Chelsea Hospital for Women. The Duke of Sutherland has lent Stafford House for this the last of Mr. Bancroft's interesting series of readings.

MR. ALEXANDER PROFEIT, A.M. King's Coll., Aberd., L.R.C.S. Edin., J.P., who for the past twenty years was commissioner on Her Majesty's estates at Balmoral, Abergeldie, and Birkhall, died on Wednesday at his home, Craiggowan House, Balmoral. Mr. Profeit was at the beginning of his career a medical practitioner.

THE PRINCE OF WALES has graciously consented to lay the foundation-stone of the new buildings of the Royal London Ophthalmic Hospital, Moorfields, shortly after Easter, and it is understood that the Princess of Wales will probably accompany him. In the meantime an influential meeting in aid of the funds is to be held at the Mansion House on Monday, Feb. 1st.

THE Mercers' Company have granted £1000, the Skinners' Company £100 for three years, the Governors of the Bank of England £100, the Salters' Company 25 guineas, the Girdlers' Company 25 guineas, the Vintners' Company 20 guineas, and the Broderers' Company 10 guineas to the special appeal fund of £100,000 now being raised on behalf of Charing-cross Hospital.

PRINCESS CHRISTIAN has, at the request of the Queen, consented to open the new General Hospital which is being erected at Birmingham at a cost of nearly a quarter of a million sterling. The institution is expected to be ready for opening early in June, and the cost, less about £40,000, has been subscribed.

A MEETING of the medical profession will be held at St. Martin's Town Hall, Charing-cross-road, London, on Thursday next, Feb. 4th, at 4 P.M., to discuss the question of Hospital Abuse and the recommendations of the Hospital Reform Association.

THE festival dinner in aid of the funds of University College Hospital will be held at the Hôtel Cecil on Wednesday, Feb. 10th, when the Right Hon. the Lord Mayor of London will preside.

LORD SALISBURY has confirmed the intention of the Government to bring in, should time admit, a Bill for Amended Legislation for Habitual Drunkards during the current session.

MISS BEATTY, the plaintiff in the recent action against Dr. Cullingworth, has, we are informed, decided to carry her appeal to the House of Lords.

THE Semi-Centennial Celebration of the New York Academy of Medicine takes place to-day (Friday) at the Carnegie Music-hall.

THE DUCHESS OF TECK has consented to open the enlarged Leyton and Walthamstow Hospital on Thursday, Feb. 11th.

AT the meeting of the Linnean Society, held on Jan. 21st, Robert Barnes, M.D. Lond., was admitted a Fellow.

LITERARY INTELLIGENCE.—The first weekly part of a people's edition of Cassell's "Old and New London," including "Greater London," is now on the eve of publication. It contains a large coloured map of London, scale four inches to the mile, brought up to date as far as practicable, and clearly showing the railway stations, tramways, parks, public buildings, theatres, &c., of the metropolis.—Early in summer the Scientific Press will issue a book entitled "The Menopause and its Disorders," by Dr. Leith Napier.

Hosted by Google

Pharmacology and Therapeutics.

THE ACTION OF PILOCARPINE IN EXCESSIVE SWEATING.

THE *Therapeutic Gazette* recommends the use of minute doses of pilocarpine for excessive sweating. It has been found that while the ordinary dose of pilocarpine will cause sweating a very small dose—such as $\frac{1}{10}$th to $\frac{1}{15}$th of a grain—often has the opposite effect. This action has been found useful in a certain number of cases of pulmonary tuberculosis to control the night sweats, and these small doses have not been accompanied by any unpleasant symptoms—such as increased salivary flow and general depression—which often follow when the drug is given in larger amounts. The writer of the article thinks that this might be a remedy worth trying in obstinate cases which have failed to yield to other methods of treatment. Proben, in the *New York Medical Journal*, warns the profession against the routine use of pilocarpine in uræmia, which, in his experience, has proved both untrustworthy and dangerous. The bad effects are ascribed to the cardiac failure which is apt to take place on account of the degeneration of the heart, which so often accompanies cases of chronic nephritis.

METHYLENE BLUE AS A THERAPEUTIC AGENT.

Berthier states that methylene blue may be used with advantage in cases of gastric hyperacidity. The dose recommended is from one to three grains each day for several days. It is then discontinued for a few days and afterwards used again. It is said that under this treatment the pain and vomiting disappear and normal digestion becomes re-established. The *Journal de Médecine de Paris* states that Netchaieff has used methylene blue in acute and chronic cases of Bright's disease, and a case is reported which improved greatly after taking one and a half grains of methylene blue daily for some time. Methylene blue is an aniline derivative in the form of bronze-green crystals forming an intense blue solution in water. The dose ranges from one to four grains. The urine of patients who are taking this drug is coloured blue and the fæces become blue on exposure.

THE TREATMENT OF EPILEPSY BY SULPHATE OF DUBOISINE.

Cividali and Gianelli report that sulphate of duboisine diminishes the number and intensity of epileptic attacks. The drug was administered in doses of 1-120th of a grain, increased to 1-60th, and the most favourable results were obtained in the cases of epilepsy associated with psychical disorders.

THYROID TREATMENT IN THE IDIOPATHIC TETANY OF CHILDREN.

Dr. Lacone Maestro is said to have applied the thyroid treatment to tetany with some success. The thyroid gland was given raw or slightly cooked, and the dose, small to begin with, was gradually increased to thirty grains a day. Although only three cases were tried, the result seemed definite enough to allow the following conclusions to be made. The thyroid treatment is well borne by children, and the digestive functions and diuresis are not notably influenced by it, and it is only in certain cases that it is necessary to suspend the treatment from time to time. In idiopathic tetany the administration of thyroid gland was found to diminish the intensity and frequency of the attacks and shorten the duration of the disease, while at the same time this treatment is not opposed to the symptomatic treatment, as it does not present any incompatibility with the methods ordinarily employed.

SUB-CONJUNCTIVAL INJECTIONS OF SODIUM CHLORIDE IN VARIOUS OCULAR DISEASES.

Dr. Veasey, writing in the *American Journal of Ophthalmology* on this subject, thinks that subconjunctival injections of sodium chloride produce quite as good results in the treatment of ocular affections as solutions of mercuric chloride, for he thinks that the benefit which may follow such injections results from the irrigation of the engorged lymph channels, and not from the specific action of the mercury on the inflamed parts. Sub-conjunctival injections of sodium chloride produce much less discomfort than mercury, and have been found of special value in relieving the pain of iritis and also in promoting the rapid absorption of sub-conjunctival hæmorrhages.

TURPENTINE IN ACNE ROSACEA.

A patient who was suffering from bronchitis as well as acne rosacea was given turpentine as an embrocation for his chest, and when it had produced the desired effect he took it into his head that what was good for his chest might prove useful for his face, which had been affected for a long time and appeared to be quite incurable, as a great many remedies had been tried unsuccessfully for it. The result was that the acne disappeared. His medical attendant, Dr. Betz, being greatly surprised at the result tried the same remedy on other cases of acne rosacea and found it very efficacious. The application causes, as might be expected, violent smarting and redness, which, however, disappear in a few hours. Dr. Betz suggests that the turpentine has a solvent action on the sebaceous secretion and that it produces a beneficial hyperæmia in the dermis, and, lastly, that it also exerts a disinfecting action which prevents the spread of the affection.

ARTIFICIAL SERUM IN SKIN DISEASES.

Subcutaneous injections of so-called artificial serum—that is to say, a solution of chloride and bicarbonate of sodium—have been employed by Dr. Tommasoli of Palermo with considerable effect on some cases of inveterate skin disease in his dermatological clinic. The effect which is generally attributed to "artificial serum" is that of stimulating the secretory and excretory processes of the body and of increasing its vital energy, and as these indications exist in many skin diseases it appeared probable to Dr. Tommasoli that he might in this way benefit his patients. No difficulty was experienced in administering the injections, which varied in quantity from one to seven ounces at a time, and in no case were any after ill-effects produced. Great improvement was effected in two cases of chronic eczema after less than thirty injections. A case of general folliculitis was completely cured by twelve injections, and one of senile genito-anal pruritus, which had lasted for thirty years, was cured in forty-four sittings; lastly, a case of lichen planus, with a great deal of itching, was cured in five weeks by thirty-three injections. On the other hand, however, no improvement was produced in fungoid mycosis, diathetic pruritus, pemphigus, lupus, syphilis, or in some cases of eczema.

STIVEN *v.* WELSFORD.

IN a recent issue of THE LANCET[1] we noticed briefly the circumstances relating to the trial of this action, which occupied the court for eight days, but inasmuch as leave was given to appeal against the verdict we abstained from commenting on the merits of the case. Litigation having, we believe, terminated we are no longer bound to silence. Seldom has it been our lot to chronicle such bitter strife between professional brethren and never to contemplate more contradictory evidence as to facts. The jury had a most unenviable duty, but since they have delivered themselves upon oath it would be invidious to challenge their verdict. Counsel for the plaintiff sought to explain the large discrepancies, not by alleging false swearing on the part of defendant's chief witnesses, but by assuming that the patient was from the natural effects of his illness incapable of accurate observation and reliable reasoning, and that his wife, on account of the physical and mental strain upon her, was under like disability. Mr. Justice Pollock, who presided at the trial, took a less liberal view and directed the jury to find on which side the truth lay.

The action was for slander alleged to have been uttered by Dr. Welsford against Dr. Stiven, who had professionally attended Dr. Welsford's brother. The main pleas for the defence were privilege and justification. On Dec. 11th, 1895, Mr. Welsford was seized with illness the chief symptoms, of which was abdominal pain. The attack eventually became an undoubted one of appendicitis, with consecutive perityphlitic abscess. Two equivocal symptoms, excess of lithates in the urine and derangement of the function of the bladder, led Dr. Stiven to diagnose "lithæmia." The intestinal disturbance he explained by errors in diet recent and remote, with their consequences, constipation and flatulence. It was not until the night of

[1] THE LANCET, Dec. 19th, 1896, p. 1772.

Hosted by Google

the ninth day of the illness that Dr. Welsford saw his brother and then definite regional signs were manifest and notably swelling in the right iliac fossa. According to Dr. Stiven these were not present on the morning of that day. Guided by his diagnosis Dr. Stiven ordered on Dec. 12th half an ounce of castor oil and a seidlitz powder; on the following day the oil was repeated; from Dec. 16th to 19th a mixture containing half a drachm each of the sulphates of soda and magnesia was administered every six hours. On Dec. 19th tincture of rhubarb and potash was substituted. To relieve the patient's suffering five minim doses of tincture of opium was prescribed on Dec. 11th and 12th. This was replaced by hyoscyamus on the 13th and these again by bromide upon the 14th to the 18th; and on the 19th chloral, bromide, and morphine. A hypodermic of morphine was injected on Dec. 11th. Finding that opium disagreed with the patient the other above-named sedatives were resorted to. On Dec. 20th Dr. Soltau Fenwick was called in and the diagnosis of perityphlitis was confirmed and opium pill, gr. ¼, every six hours constituted the chief element of treatment. Even then surgical interference was not deemed necessary, but two or three days later Mr. Horsley let out 10 oz. of pus and found the appendix sloughed off and three necrotic patches in the cæcum, which eventually led to perforation.

The allegation was that Dr. Stiven had been guilty of gross carelessness and malpraxis; first, in that he failed to recognise the case as one of appendicitis; second, that what he mistook for lithæmia was merely an excess of lithates dependent on the febrile state; third, that he directed massage to be practised and himself "pummelled" the abdomen; fourth, that he improperly administered purgatives; and fifth, that he had countermanded the opium prescribed at the consultation and so had been guilty of a breach of etiquette. To these charges he replied in his defence that there was no evidence of appendicitis until the day of Dr. Welsford's appearance on the scene, although he had carefully examined the abdomen; that there was undoubted proof of the existence of lithæmia as shown by the condition of the urine, by the passage of a small calculus, and by the "stammering of the bladder"; that the alleged order of massage was merely a direction to the nurse to press over the left groin in order to facilitate the passage of an enema; that the administration of aperients was correct treatment; and, finally, that he temporarily stopped the opium on account of untoward symptoms which he attributed to its action, contending that he was not bound by the acquiescence he gave to its use decided upon at the consultation.

Graver indictments than the above could not well be levelled against a medical man, and at once we say Dr. Stiven's professional credit must for ever have been undermined unless he challenged proof of the sufficiency of the grounds on which they were made. Issue was joined in the action at law by the defendant pleading justification.

As regards the matter of ethics and law arising in the case we would first direct attention to the countermanding of the administration of opium. Any course of treatment agreed upon at a consultation is supposed to be carried out subject to the discretion of the medical man in charge of the patient. To limit his freedom of action might be to jeopardise the patient's health or life, and provided he acts in good faith, which must be assumed until the contrary is proved, no suspicion of disloyalty, and thus a breach of professional etiquette, ought to be entertained. Dr. Welsford seems to have concluded that Dr. Stiven had been disloyal, founding his judgment, no doubt, on the fact that Dr. Stiven had demurred to the opium treatment both at the consultation and on a previous occasion. But it is one thing for a person to give a tardy consent to a procedure he deems of questionable propriety and quite another to wilfully countermand such procedure from mere personal misgivings as to its desirability.

A consultation implies a divided responsibility, but this ceases when new factors intervene to change the aspect of affairs obtaining at the time of the conference. The medical man in direct charge of the patient is then unfettered to act as his conscience and judgment dictate. Rightly or wrongly, as regards the observation of facts, Dr. Stiven must be credited with having conscientiously dealt with a privilege, nay, discharged a duty. That on an earlier date he had substituted other sedatives for opium is presumptive evidence that he believed the latter drug did not agree with his patient; moreover, it was admitted that he demurred to its exhibition at the time of the consultation, and there was his sworn testimony at the trial.

The law holds that a medical man is bound only to act with reasonable care and skill. Even where the rules of procedure in a given case are laid down in definite terms it would be unjust to demand the highest attainable performance. It is much to the credit of the great body of general practitioners that charges of negligence and carelessness in the discharge of their vocation are most infrequent. Even where a medical man has apparently stepped beyond the frontier of professional duty charity bids us look with a lenient eye.

We freely admit that Dr. Welsford was sincere in his belief that his brother had not received proper attention and skill at the hands of Dr. Stiven. Distraught with anxiety as to the issue of the illness he might have given utterance to expressions of dissatisfaction which upon reflection might have seemed to him intemperate, but after the disturbing influences of thought and judgment had passed away he continued of the same mind and persisted in the same action. We cannot blame him for holding an honest opinion, or for the execution of what he conceived his duty, but we pity him in that he did not see his way to extenuate what he held to be the shortcomings of a brother practitioner. To carry his convictions, or allow them to be drawn, into the cold atmosphere of the law-courts was to expose himself to an ordeal from which he could not reckon on emerging faultless and unscathed. Of course, it was imperative to pursue the course he had opened or to retire with the acknowledgment that he had acted, if not wrongly, at least not wisely. We doubt not that the parties to the suit would have been better advised had they appealed to the arbitrament of a medical commission. A court composed of the highest professional learning and probity would have been more fitted to try the issue than a special jury of laymen. Thus much for the ethical and legal features of this melancholy exhibition. The medical aspects of the patient's illness, as judged by the testimony of the medical men—apart from that of the individuals immediately concerned—compel us to pause and compare the past and present schools of thought and practice with reference to a set of conditions described collectively as "typhlitis," "perityphlitis," and "appendicitis."

Five-and-twenty years ago much that is now held as permissible or imperative in the treatment of "appendicitis" would have been considered rank heresy. We do not hesitate to say that if many of the experts who gave evidence at the recent trial had been candidates for a diploma at the former period and had delivered themselves of their present opinions they would have stood in dire peril of being referred to their studies. What, then, has been the reason of the shifting voice of the profession with regard to the disease in question? At a cursory glance it might have been thought that a structure so definite in its anatomy and comparatively easy of access would be unlikely to present difficulty in the diagnosis of disease, or, the diagnosis being made, that there could be sharp contention as to the treatment. Much has been done of late years in the investigation of the causes, symptoms, diagnosis, and treatment of "appendicitis;" accumulated observations have more fully revealed the disorders that simulate it; and the advance of abdominal surgery has thrown much light on the history of its several phases and stages. The "rest and be thankful" line of treatment of former days has to a great extent given way to active interference, and doubtless many lives are now saved which formerly would have been sacrificed to abandonment. Great reforms very often, however, bring great abuses and rash temerity undoes the promised good. Whereas in earlier days opium was the sheet-anchor of appendicitis, the tendency now is to limit its exhibition, and there are those who discourage its use altogether. The cause of this revulsion is partly explained by the fact that appendicitis proper has been shown to cover a large number of the cases described as "typhlitis" and "perityphlitis" in which an overloaded state of the colon is a common antecedent and cause. In all cases opium is suggested—(1) by the pain and (2) by the inflamed and consequently paretic state of the muscular coat of the bowel. It is like a splint to a broken bone, and were there no contra-indications it would still enjoy universal confidence and adoption, but it checks the secretion of the mucous membrane, prevents unloading of engorged vessels, and by its narcotic influence often masks the symptoms, thus rendering it more difficult

Hosted by Google

to estimate the degree of severity of the inflammatory process and the urgency for operative interference. To show how marked has been the counter-swing of the pendulum we need only mention an incident that occurred at the late trial. Dr. Mitchell Bruce, on cross-examination, was asked if he agreed with the teaching of a well-known text-book in which great prominence was given to the opium treatment. He replied by asking which edition of the work was referred to, and on being told hoist counsel with his own petard. "In a later edition," said Dr. Bruce, "you will find it the reverse."

The prevailing opinion amongst medical men it that opium should be sparingly administered and only when specially indicated, as by severe pain. Dr. Stiven could not reasonably be charged with having obstinately set his face against the opium treatment, since he prescribed it on more than one occasion and only discontinued its use when he believed it was doing harm. A far graver allegation was that he administered purgatives which seriously aggravated the disease; and the adoption of the "aperient" treatment was adduced as evidence that through carelessness he failed to recognise the nature of the malady. There was some conflict of testimony on the general question of the use of aperients in appendicitis. Four surgeons and three physicians from separate London medical schools were of opinion that aperients—not drastic purgatives—were generally advisable, and that the particular drugs and the quantity in which Dr. Stiven prescribed them were appropriate to the case, as put before them on behalf of the plaintiff.

From this narrative of the general principles of the medicinal treatment of appendicitis now current and of the particular method adopted by Dr. Stiven it must be conceded that two of the grounds of the charge of malpraxis were practically disposed of. The statements that Dr. Stiven pummelled the abdomen and ordered massage he directly denied, and the jury by their verdict believed him. The question as to whether the appendicitis dated from Dec. 11th or supervened several days later is perhaps somewhat doubtful. The condition of the appendix and the colon and the size of the abscess found at the operation would seem to suggest an earlier date than the 19th or 20th, but knowing how sudden the incidence and how rapid the development of appendicitis frequently are we are debarred from giving an authoritative opinion. The difficulty of absolutely diagnosing the state of affairs is shown by the fact that at the consultation two days prior to the operation, when ten ounces of pus were evacuated, no abscess was discovered, although it probably existed, but was obscured by flatulent distension of the colon and by the presence of gas outside it. If all the cases of mistaken identity in the investigation of supposed cases of appendicitis were collected the list would be a formidable one. We have known instances where an operation has revealed a tuberculous abscess; and again where the symptoms of early appendicular disease were prominent, and yet nothing wrong was found on dissection. Many of the symptoms in Mr. Welsford's case—pain in the abdomen, disturbance of the function of the bladder, and the passage of lithates in considerable quantity—were consistent with Dr. Stiven's diagnosis; equally they were covered by the conditions incidental to appendicitis. If, as alleged, a small calculus was actually passed—this was denied by the defendant—the event would naturally weigh heavily in Dr. Stiven's mind, considering the diagnosis he had made.

The term "lithæmia" is not a happy one, and, as Dr. Fenwick, sen., said, it has to a great extent fallen into disuse. It was originally intended to indicate the condition of the blood in the gouty diathesis, but it came to have a looser meaning and has, though erroneously, been applied by some to all cases in which there is excess of lithates in the urine. Dr. Stiven seems to have employed it in the more restricted sense, but it is only just to remark that the defendant contended that the "lithæmia" in his brother's case was only excess of lithates from the febrile state. The name matters little in itself, but a great deal depended on its use in this trial, for it raised the question, "Did Dr. Stiven mistake febrile urine passed by a patient suffering from appendicitis for evidence of a totally different condition and thus make a wrong diagnosis?"

After careful and anxious study of the evidence we feel compelled to subscribe to the verdict in Dr. Stiven's favour. We deeply deplore the litigation, which we hope and trust will be the means of fostering charitableness between medical brethren and act as a deterrent against unjustifiable slander.

THE PROPOSED CENTRAL HOSPITAL BOARD FOR LONDON.

THE Council of the Charity Organisation Society held a special meeting on Monday, Jan. 25th, at the Royal United Service Institution, "to consider the question of a Central Hospital Board for London and to appoint a general committee to promote its establishment." Members of the medical profession throughout London had been invited, and of these there was a very large and representative attendance. The proceedings, over which the Earl of Stamford presided as chairman, opened with the reading of a number of letters of apology for absence. Princess Christian expressed her great regret at being unable to attend. The Duke of Bedford wrote sympathising "with the idea of organisation." The Duke of Fife, offering to render what assistance he could to the scheme, said he "heartily sympathised with its objects and wished it every success." Lord Cranbrook wrote saying he felt "that some central authority is needed to prevent waste and overlapping." Sir James Paget said, "I think that very useful results may be attained if the plan proposed in the draft scheme which you sent to me be adopted and its rules be carefully observed." There were also letters from Mr. Gladstone, Lord Meath, Sir Edward Sieveking, Sir James Crichton Browne, Mr. G. D. Pollock, Dr. Lauder Brunton, and others. The letter of Dr. Lauder Brunton contained a short statement of his views on the subject of the meeting. His general view, he said, was that by means of coördinated action between the various hospitals of London a greater amount of good might be effected and less harm done in the way of allowing the hospital relief which was intended for the necessitous being shared to an undue extent by those who were able to pay for medical assistance. To insure the success of any such scheme it was obvious that it must meet with the hearty coöperation of the officials, both lay and medical, of the hospitals, more especially of the large ones. Dr. Lauder Brunton then went on to examine the draft scheme and to criticise it, and having done this he recommended that instead of pressing the adoption of the scheme now it would be best to be content with (1) re-affirming the decision of the previous meeting that a Central Hospitals Board for London was desirable; (2) that in it the medical and lay elements should both be represented; and (3) that the governing bodies of the various charities in London should be approached with the object of learning their views regarding the constitution of such a board and their willingness to coöperate in its formation.

The CHAIRMAN made a short introductory speech. For many years, he said, the incidental evils in connexion with the system of hospitals had been fully admitted. Special attention was called to them in the report of the House of Lords Committee in 1892, and the Charity Organisation Society had upon several occasions held special meetings of the Council upon the subject, the standpoint of this society, of course, being the interests of scientific charity—the desire that the suffering poor should be helped from available resources in the wisest possible way. It was, perhaps, as well to remember that the object for which hospitals were founded—the primary object—was the need of the suffering poor; but, of course, other interests were concerned in the matter, and the abuses which had arisen in connexion with medical relief deeply affected certain classes of the community, especially the abuses which were admitted to exist in connexion with the out-patient departments. The authorities of the hospitals themselves felt that there was a general public sentiment that a more satisfactory state of things ought to exist, and that the appeals which were put forward on behalf of hospitals in difficulties might be more fully responded to if there was some sort of central advising board which would instruct the public as to where funds were really most of all needed. It was nearly a year since he presided at a meeting at which the principle was affirmed that a central hospital board for London was desirable, and this meeting was called in the view that possibly the time might now be ripe to give further effect to that resolution and to appoint a committee to promote it. The object of the meeting was merely to appoint a committee which would pave the way for the establishment of a

Hosted by Google

Central Board. It might be useful, however, to lay stress upon some of the principal points of the scheme which had been drafted. It was regarded as very essential that the voluntary system of medical relief should be preserved. The second object of the scheme was to give assistance to medical charities by means of a common fund for special purposes which would conduce to the improvement of medical relief in the metropolis as a whole. When he spoke of special purposes he meant such things as building extension, which could not be met by grants from the Hospital Sunday and Saturday Funds. The third object was to provide some machinery for regulating and improving the existing voluntary system. There was no intention of interfering with the self-government of individual medical charities or of intercepting donations to be given to them. The Board should be an influential body and should have at its disposal funds to enable it to make these special grants as well as the services of responsible visitors. It should have no compulsory powers, but should simply influence the public and the hospitals by the issue of an annual report. The duties of the Board would be, roughly, to obtain special reports and returns, require proper audit of accounts, visit and report upon each charity, and report upon the establishment, or removal, or enlargement of hospitals. The scheme was not submitted as a cut-and-dried proposal, but as a basis for consideration and discussion by the general committee which this meeting would be asked to appoint. It was hoped that the general committee, possibly through a small sub-committee, would approach the schools and hospitals and other bodies interested and in other ways promote the end desired.

Sir WILLIAM BROADBENT moved: "That this meeting affirms the resolution adopted on April 13th last approving of the establishment of a Central Hospital Board for London on a representative basis, and accepts the draft submitted to it as indicating a plan that, subject to further consideration and modification, is likely to prove satisfactory, and that the following be a General Committee to consider, promote, and from time to time report upon the draft scheme, with power to add to their number, and to appoint an Executive Committee." The names of the Committee were then read out. Sir William Broadbent, in continuing, insisted that nothing in the proceedings of this meeting could be taken as hostile to hospitals. It was no longer necessary to dwell upon the abuses that had arisen in connexion with these institutions, for they were known to every one present. It was impossible that the number of out-patients in particular seen every year, amounting to something like 1,300,000, could represent only those who were fit objects for medical and surgical relief, and it was matter of notoriety, and was well known to every hospital physician and surgeon, that, do what they might, patients came to hospitals who did not belong to the proper hospital class. This matter, of course, affected very closely the medical profession. It concerned primarily the general practitioners, who suffered seriously from the fact that patients who were able to pay for medical advice got it gratis at hospitals, and it concerned also hospital physicians and surgeons, who felt that they were sometimes made the instruments of inflicting a wrong upon their professional brethren. This might not concern the public very closely, but hospital subscribers would object, and did object when they knew of it, to paying for the medical advice of people who could quite as well afford to pay for it as they could themselves. It was acknowledged on every hand that there was a waste of energy on the part of physicians and surgeons of hospitals, that there was a waste of money on the part of supporters, and, worst of all, that there was a waste of time and infliction of great injury upon the poor patients. One of the main causes of the present unsatisfactory state of things was undoubtedly the isolation of the great hospitals from each other and the competition which had sprung up among them. There was no inter-communication, no comparison of work, or comparison of methods among them. Every hospital had endeavoured to solve its difficulties in its own way, and in consequence there had arisen differences and divergencies which had left gaps, and these gaps had sometimes been filled by small institutions, many of which had done great harm. One serious mistake hospitals made originally was in not recognising early the necessity for specialties. With every advance in surgery and medicine certain necessary specialties were developed, but the hospitals were not quick enough to recognise the necessity and provide for it, and in that way special hospitals arose. He had never been one to object to special hospitals. He had always recognised their merits and their necessities, but one must add that the special hospitals had been particularly liable to abuse and some of the worst evils of out-patient practice had arisen in connexion with them. The coördination proposed would not interfere with the individual life of the hospitals. Their autonomy must be respected. There was no idea of extinguishing the healthy rivalry between them but the rivalry must be in the direction of the good of the patients and not merely of increasing the numbers and being able to put forward specious claims to the support of the public founded on numbers and not founded on efficiency and the value of the work done. For his own part he should like to see local as well as general coördination. He should like to see each large hospital with its medical school a centre of usefulness, with which should be affiliated in the first place the provident dispensaries. It should not be forgotten that provident dispensaries represented men of the better and more highly principled among the working classes, who were willing to pay for their medical advice, and he should be prepared to give these men some preference in the matter of hospital consultation or hospital treatment. He would also do something for friendly societies, which, be it remembered, actually helped hospitals from their funds. There might also be organisation and inter-communication with the special hospitals in the locality. All this demanded some sort of central institution. What they wanted was "a hospital brain," which should receive information from every source and impart instruction derived from its experience. As to the draft scheme, no doubt modifications had occurred to all of them, but it had been formulated merely for the purposes of discussion, and it might emerge from the consideration of this committee something totally different. With regard to the funds necessary for the scheme it was hoped that other sources of supply might be tapped besides those at present open for the relief of hospitals. It had occurred to him that there was a possibility at any rate of a gigantic scheme of collecting money for the benefit of the London hospitals on the part of the Prince of Wales in celebration of the Queen's reign. His Royal Highness had, so to speak, put Guy's Hospital on its feet again, and he thought that this new scheme was worthy of the Queen, worthy of the Prince, and worthy of the occasion, and he only hoped that the rumours they heard might turn out well founded and that the scheme might have every success. If that money was collected there must be a committee of distribution. That committee would be in a way a central hospital board for the particular occasion. It must, in order to make the distribution effectual, obtain information from all the hospitals and must distribute the money, not merely in relation to the apparent necessities of the hospitals, but with some recognition of the merits of the different institutions which were to be supported. It seemed to him possible that this Central Board, which it must be for the occasion, might turn out to be the Central Board which they all desired to see, and if the principle of representation laid before them by the Charity Organisation Society could be carried out on the committee he thought it would be the best way to secure the proper distribution of the funds.

Mr. VICTOR HORSLEY seconded the resolution in a few sentences, his wish being, he said, to give those opposed to the principle it contained an opportunity of expressing their views to the meeting.

Mr. MYERS, seconded by Mr. GRIFFITH GRIFFITH, moved as an amendment: "That the Charity Organisation Society draw up recommendations to the boards of the London hospitals, &c., to enable these boards as much as possible to compare their relative expenditure and to profit when expedient thereby, and also to enable the Charity Organisation Society to draw up accurate annual reports and statements of accounts of these charities. That this society issue such advice as they may deem expedient for the better regulation of the out-patient departments of the various hospitals and dispensaries." Mr. Myers said he did not think the experience of central boards so satisfactory that they should attempt to create a new one, and with regard to finance he contended that in course of time the proposed board would divert contributions from the individual hospitals and increase their financial difficulties.

Mr. LOCH, secretary of the Charity Organisation Society, in reply to a question put to him, said that the desire was in the first instance to get the opinion of medical men upon the scheme, and then to submit it through the proposed committee to the governing bodies and officers of the hospitals.

Hosted by Google

The Reverend Dr. WACE, chairman of King's College Hospital, expressed the view that further time should be given for the consideration of the scheme.

The amendment being put to the meeting was negatived by a large majority.

Another amendment affirming the resolution of April 13th, and suggesting that all further steps for the establishment of a central board should be taken by a committee of representatives elected by the individual hospitals, was moved and was also negatived by a large majority.

Sir WILLIAM BROADBENT'S motion was then put to the meeting and carried by 121 votes to 12.

BUBONIC PLAGUE IN BOMBAY.

WHAT with the disastrous outbreak of plague in Bombay, the terrible famine in India, the natural alarm of the European Powers and of our own Colonial Governments lest the plague should be introduced into their midst, and the enforcement everywhere of quarantine regulations against India, with the consequent paralysing effect on trade and commerce—not to mention other matters of more or less gravity—the Government of this country is at the present moment confronted with graver difficulties than any Government has encountered for some time past. We need now, if ever we did, a strong and wise Administration and an abstention on the part of the Opposition from exhibiting any captious party spirit. We may all, whatever may be our politics, rejoice that such an attitude as that last referred to has been adopted.

According to the latest returns it is computed that since the plague was officially recognised in Bombay, and despite the decrease in the population, close upon 10,000 deaths have occurred in excess of the average for the last five years. This excess may, it is believed, be fairly attributed to the presence of plague in that city. The great gravity of the situation has been fully recognised by the India Office at home and by the Viceroy's Government of our great dependency. Happily, it is not the habit of the people of this country to "lose their heads" in the presence of difficulties, but to rise to the occasion and make all the attempts in their power to meet and overcome them. Immense energy has been displayed and vigorous action has been taken, and large sums of money have been voted in view of preventing the epidemic from spreading on the one hand and of accommodating and succouring those afflicted with the disease on the other. It seems to us that, practically speaking, the measures which we sketched last week have been put in force. Medical and sanitary committees have been formed and have been energetically working; numerous isolation hospitals have been opened for the sick, and temporary accommodation for the infected or healthy; house-to-house visitation of all infected districts has been instituted, and all persons affected by the disease have been removed and segregated; infected houses have been demolished and open-air spaces and vastly increased ventilation provided; the railways are guarded against infection by medical inspection; measures for the all-round cleansing and disinfection of the city have been vigorously carried out under the advice of experts and of the best medical authorities, experienced organisers, and administrators that India could supply. In the case of pilgrims to the Moslem holy places the law has been put in force to prevent the disease being carried into the Red Sea. All pilgrimage from infected ports is to be stopped, and all persons, natives and others, proceeding by road, rail, or river are medically inspected on every available opportunity. It is only fair to the Government of India and the local authorities to ask what more could be done than has already been, or is being, done? The disease has, speaking relatively, affected but few Europeans, and the sickness and mortality amongst the dock labourers and Port Trust servants have been very small indeed. This fact supplies a standard in the way of sanitation and personal hygiene to the level of which the authorities must strive to attain for all classes alike. The reason why Bombay has been so sorely stricken is most probably attributable to previous chronic neglect of those sanitary and common-sense precautions which cannot be disregarded with impunity. Still, considering that Bombay is a big Eastern city, inhabited by a large and poor native population with numerous caste prejudices, into the midst of which the plague-cause was introduced, we cannot fail to notice that the modern methods of dealing with epidemic disease are all in the right line. Plague is probably about as fatal as ever it was in those whom it attacks, but the dimensions of an outbreak are much more under control than they were. The sickness and mortality at Bombay, bad as these may be, compare very favourably with what they were two centuries or less ago, when sanitation was unknown, and what to do, or to strive to do, in an epidemic, except to flee from the scene of it, was also either unknown or based upon purely empirical ideas.

Beyond the virulent but limited outbreak at Karachi and that at Poona, with a few cases at other places whither the panic-stricken native population of Bombay had fled, carrying the disease with them, we do not hear of any widely spread prevalence or manifestation of the disease. Contagious the plague undoubtedly is, but, like other epidemic infections, it fails to secure any firm foothold where the conditions are unfavourable to its growth and development. It is an exotic, which requires to have what we may term a muck-heap or hot-bed in the shape of a suitable environment prepared for its reception and growth.

All the Great Powers have assented to the project of an International Sanitary Conference at Venice to concert measures for preventing the introduction of the plague into Europe, which is to meet next month. Dr. Druetti, sent by the Italian Government to watch the progress of the plague in India, has arrived at Bombay. A special sanitary mission, accompanied by a French delegate, has been sent by the Medical Board in Egypt for the stations on the coast of the Sinai Peninsula to determine the measures that are deemed necessary to secure the immunity of Egypt from contagion, and there is generally a good deal of anxiety and activity displayed by the Continental Powers regarding the possible spread of the epidemic from Bombay.

ARMY MEDICAL DEPARTMENT REPORT FOR THE YEAR 1895.[1]

[FIRST NOTICE.]

THE Army Medical Report is now issued in two separate volumes—one as a blue-book for presentation to the Houses of Parliament consisting only of the official reports and statistical tables; the other of these and also of an appendix containing various professional reports and papers by officers of the Medical Service on subjects of a more technical and scientific character such as are of interest to the Department and medical profession, but which do not directly concern Members of Parliament and non-medical officials.

The report for 1895 leads off with the usual summary statement on the "Health of the Troops at Home and Abroad." This statement condenses the general information in such a way that it serves to focus the attention of the reader on the main points connected with the health of the army as a whole during the year under review, and we cannot, therefore, do better than adopt it as introductory to our notice.

The average annual strength of the troops serving at home and abroad in 1895, as computed from the returns received by the Army Medical Department, was 200,681 warrant officers, non-commissioned officers, and men (exclusive of colonial corps); the admissions into hospital in this force were 199,312 and the deaths 1669. The rates represented by these numbers are for admission into hospital 993·2 and for deaths 8·16 per 1000 of the average annual strength, the latter being calculated on the strength of 204,592, which includes detached men.

The statistics of the troops serving in the United Kingdom during the year show that the ratio of sickness and mortality were somewhat higher than in 1894, but still below the average. Only 3 cases of small-pox occurred, as compared with 11 in the year before, but scarlet fever and measles were more prevalent. Enteric fever gave practically the same ratio as in the previous year, Dublin being the station most affected. There was a considerable increase in the admissions for influenza, but a decline in those for venereal affections.

In the Colonies, as a whole, the general health was not so good as

[1] Army Medical Department Report for the Year 1895, with Appendix, Vol. xxxvii. London: Printed for Her Majesty's Stationery Office by Harrison and Sons, Printers to Her Majesty. 1896. Price 4s.

Hosted by Google

in 1894, continued fevers being more prevalent at Malta, enteric fever at Bermuda, and malarial fevers at Mauritius, and a large increase occurred in the Straits Settlements in the sickness from venereal diseases. In the West Indies and China the admission ratios were lower than in the year before, while at Gibraltar there was but little change.

In India there was a decline in the sick rate as compared with that for the previous year, but a slight increase in comparison with the average ratio. Cholera and malarial fevers caused less sickness than in 1894, but there was an increase in the amount of venereal disease.

The health of the troops in Egypt was good and the improvement noted in last year's report continued, though in a lesser degree.

Among the papers in the appendices—sixteen in all in number—to which medical readers naturally turn with most interest thirteen are contributions by medical officers and by the professors at Netley. Among these we may refer to the Report on the Progress of Hygiene for 1896; the list of operations at Netley; a report on the Ashanti Expedition of 1895–6; various papers on medical, surgical, and pathological subjects; and one by the Professor of Pathology at the Army Medical School on the Pathology and Therapeutics of Scurvy. These we shall consider subsequently.

Glancing at the table of statistics of some of the most important of the results of sickness of every command in which the troops were stationed we find that the total mortality on an annual average strength of 200,681 was 8·16 per 1000, and of the army at home it was 4·32. Gibraltar is, as regards mortality, a healthy station compared with Malta, the death-rates being respectively 3·84 at the former and 6·87 per 1000 at the latter station. Mauritius, as regards admission-, death-, and invaliding-rates, heads the list in point of unhealthiness, India next, followed by China; whereas Canada is, except in point of mortality rate, the healthiest of the foreign stations. Of the home stations Scotland is the healthiest; and Ireland has the highest death-rate, but a lower admission and constantly ineffective rate than England and Wales. Speaking generally, the causes of inefficiency at the several stations at home and abroad are very much the same as they were in previous years. Typhoid fever remains the great and increasing cause of mortality in our European army in India, and, as everyone knows, venereal disease is the great and increasing cause of sickness and inefficiency in that command. We have already had occasion to call attention to the gravely increased prevalence of this disease among the population of the Straits Settlements and Malay peninsula.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6310 births and 4156 deaths were registered during the week ending Jan. 23rd. The annual rate of mortality in these towns, which had declined in the three preceding weeks from 22·3 to 19·2 per 1000, rose again last week to 19·7. In London the rate was 18·1 per 1000, while it averaged 20·8 in the thirty-two provincial towns. The lowest rates in these towns were 12·0 in Croydon, 13·6 in Derby, 14·2 in Brighton and in Halifax, and 14·1 in West Ham; the highest rates were 23·5 in Sunderland, 23·6 in Burnley and Oldham, 26·0 in Manchester, and 29·2 in Liverpool. The 4156 deaths included 386 which were referred to the principal zymotic diseases, against 413 and 378 in the two preceding weeks; of these, 117 resulted from whooping-cough, 87 from diphtheria, 67 from measles, 43 from scarlet fever, 36 from "fever" (principally enteric), 35 from diarrhœa, and 1 from small-pox. No death from any of these diseases was recorded last week in Huddersfield; in the other towns they caused the lowest death-rates in Croydon, Hull, Halifax, and Oldham, and the highest rates in Blackburn, Burnley, Swansea, and Nottingham. The greatest mortality from measles occurred in Gateshead, Plymouth, Nottingham, and Bradford; from whooping-cough in Wolverhampton, Salford, Blackburn, Swansea, Nottingham, and Burnley; and from "fever" in Sunderland. The mortality from scarlet fever showed no marked excess in any of the large towns. The 87 deaths from diphtheria included 53 in London, 4 in Birmingham, and 3 in Liverpool. One fatal case of small-pox was registered in London, but not one in any other of the thirty-three large towns. There were 2 cases of small-pox under treatment in the Metropolitan Asylum Hospitals on Saturday last, the 23rd inst., against 2 and 3 at the end of the two preceding weeks; no new cases were admitted during the week. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital was 3354, against 3707, 3597, and 3414 on the three preceding Saturdays; 249 new cases were admitted during the week, against 271, 290, and 208 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had declined from 348 to 306 in the three preceding weeks, rose again to 325 last week, but were 407 below the corrected average. The causes of 56, or 1·3 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Cardiff, Nottingham, Newcastle-upon-Tyne, and in fourteen other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Liverpool, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 22·8 and 21·9 per 1000 in the two preceding weeks, rose again to 24·6 during the week ending Jan. 23rd, and exceeded by 4·9 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 15·3 in Perth and 16·1 in Paisley, to 28·8 in Greenock and 28·9 in Glasgow. The 733 deaths in these towns included 36 which were referred to measles, 26 to whooping-cough, 8 to diphtheria, 7 to diarrhœa, 6 to "fever" (principally enteric), and 6 to scarlet fever. In all, 89 deaths resulted from these principal zymotic diseases, against 101 and 75 in the two preceding weeks. These 89 deaths were equal to an annual rate of 3·0 per 1000, which was 1·2 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 60, 45, and 28 in the three preceding weeks, rose again to 36 last week, of which 32 occurred in Glasgow and 2 in Paisley. The 26 deaths referred to whooping-cough corresponded with the number in the preceding week, and included 20 in Glasgow, 2 in Edinburgh, and 2 in Paisley. The fatal cases of diphtheria, which had been 3 in each of the two preceding weeks, rose again to 8 last week, of which 4 occurred in Glasgow and 2 in Edinburgh. The 6 deaths referred to different forms of "fever" exceeded by 2 the number in the preceding week, and included 4 in Glasgow. The fatal cases of scarlet fever, which had been 10 and 3 in the two preceding weeks, rose again to 6 last week, of which 3 occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 152 and 162 in the two preceding weeks, were again 162 last week, and were 26 above the number in the corresponding period of last year. The causes of 32, or more than 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined in the three preceding weeks from 44·1 to 34·8 per 1000, rose again to 43·9 during the week ending Jan. 23rd. During the past three weeks of the current quarter the death-rate in the city has averaged 38·0 per 1000, the rate during the same period being 18·2 in London and 20·6 in Edinburgh. The 294 deaths registered in Dublin during the week under notice showed an increase of 61 upon the number in the preceding week, and included 57 which were referred to the principal zymotic diseases, against 40 and 47 in the two preceding weeks; of these, 23 resulted from whooping-cough, 15 from measles, 10 from diarrhœa, 4 from scarlet fever, 4 from "fever," 1 from diphtheria, and not one from small-pox. These 57 deaths were equal to an annual rate of 8·5 per 1000, the zymotic death-rate during the same period being 1·8 in London and 1·4 in Edinburgh. The fatal cases of whooping-cough, which had been 19 and 27 in the two preceding weeks, declined again to 23 last week. The deaths referred to measles, which had been 9 in each of the two preceding weeks, rose again to 15 last week. The 10 fatal cases of diarrhœa considerably exceeded the number recorded in any recent week, while the 4 deaths referred to different forms of "fever" corresponded with the number in the preceding week. The 294 deaths in Dublin last week included 51 of infants under one year of age and 57 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons considerably exceeded the

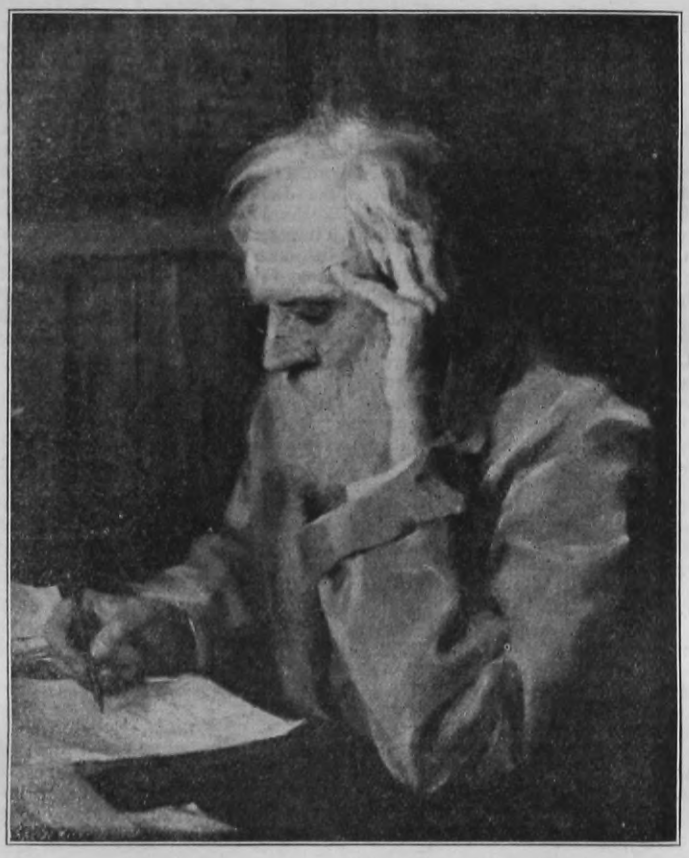
numbers recorded in the preceding week. Six inquest cases and 5 deaths from violence were registered; and 88, or nearly a third, of the deaths occurred in public institutions. The causes of 23, or nearly 8 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING 1896.

Complete statistics relating to sickness and mortality during the year 1896 in each of the forty-three sanitary areas of London are summarised in the accompanying table. The mortality statistics relate to the deaths of persons actually belonging to the various sanitary districts, and are the result of a complete system of distribution of deaths occurring in the institutions of London among the different sanitary districts in which the patients had previously resided. With regard to the notified cases of infectious diseases in London during 1896, it appears that the proportion of persons reported to be suffering from one or other of the nine diseases in the accompanying table was equal to 11·1 per 1000 of the population, estimated at 4,421,955 persons in the middle of the year. In the preceding three years the rates were 15·7, 9·4, and 9·5 per 1000 respectively. Among the various sanitary areas the lowest rates were 6·1 in St. James Westminster, 7·1 in St. George Hanover-square, 7·6 in Woolwich, 7·8 in Strand, 7.9 in Hampstead, and 8·3 in Westminster; the highest rates were 13·0 in Limehouse, 13·2 in Clerkenwell, 13·3 in Greenwich, 13·6 in St. Luke, 14 5 in Mile-End Old Town, 14·9 in Whitechapel and in St. George-in-the-East, and 16·7 in Bethnal Green. The prevalence of small-pox in London showed a further marked decline during 1896 the cases notified being only 225, against 2813, 1192, and 979 in the three preceding years; of these, 51 belonged to Islington, 18 to Lambeth, 14 to Greenwich, 13 to Camberwell, 13 to Kensington, 9 to Poplar, and 8 to Battersea. The number of small-pox patients admitted into the Metropolitan Asylum Hospitals during 1896 was 236, and only 3 cases remained under treatment at the end of the year. The prevalence of scarlet fever in London during 1896 showed a considerable further increase upon that recorded in recent years, the number of cases notified being 25,647, against 18,446 and 19,757 in the two preceding years; this disease was proportionally most prevalent in Hackney, Clerkenwell, St. George-in-the-East, Bethnal Green, Whitechapel, Mile End Old Town, Battersea, and Greenwich sanitary areas. During the year under notice 16,271 scarlet fever patients were admitted into the Metropolitan Asylums Hospitals; the number of cases under treatment, which had been 2708 at the beginning of the year, had increased to 3599 at the end of December last. Diphtheria also showed increased prevalence during 1896, the cases notified being 13,808, against 11,186 and 11,223 in the two preceding years; this disease showed the highest proportional prevalence in Chelsea, Whitechapel, St. George-in-the-East, Limehouse, Mile End Old Town, Poplar, Bermondsey, Camberwell, Greenwich, and Lewisham sanitary areas. The Metropolitan Asylum Hospitals contained 687 diphtheria patients at the beginning of 1896; 5409 cases were admitted during the year, and 829 remained under treatment at the end of December last. The prevalence of enteric fever in London showed a decline during the year under notice; amongst the various sanitary areas this disease was proportionally most prevalent in Hackney, St. Martin-in-the-Fields, Shoreditch, Bethnal Green, Mile End Old Town, Poplar, and Rotherhithe. The number of enteric fever patients in the Metropolitan Asylum Hospitals at the end of 1896 was 116; 879 cases were admitted during the year, against 675 and 844 in the two preceding years. Erysipelas showed the highest proportional prevalence in St. Giles, Holborn, St. Luke, Shoreditch, Bethnal Green, and Rotherhithe sanitary areas. The 277 notified cases of puerperal fever exceeded by 41 the number recorded during 1895; 31 belonged to Islington, 21 to St. Pancras, 20 to Lambeth, 17 to Greenwich, 16 to Camberwell, and 12 to Bethnal Green sanitary areas.

During the year under notice the deaths of 81,721 persons belonging to London were registered, equal to a rate of 18 2 per 1000, against 20·9, 17·4, and 19·4 in the three preceding years 1893–4–5. This rate was, with two exceptions, lower than in any year on record, and was 1·6 per 1000 below the average rate in the ten preceding years. In the various sanitary areas the lowest death-rates were 11·9 in Hampstead, 12·7 in Stoke Newington, 13·4 in Lee, 13·6 in St. George Hanover-square, 14·3 in Wandsworth and in Lewisham (excluding Penge), and 15·3 in Paddington. The highest rates are 22·7 in Strand, 22·8 in St. Saviour Southwark, 22·9 in Limehouse, 23·4 in Holborn, 24·0 in St. George Southwark, 24·5 in St. George-in-the-East, and 25·1 in St. Luke. Taking the five groups of sanitary areas, the rate of mortality during 1896 was equal to 16·8 per 1000 in the west, 16·9 in the north, 17·8 in the south, and 21·4 in the east and in the central districts. To the principal zymotic diseases 14,009 deaths were referred during the year under notice; of these, 3692 resulted from measles, 3192 from diarrhœa, 2931 from whooping-cough, 2663 from diphtheria, 940 from scarlet fever, 582 from different forms of "fever" (including 5 from typhus, 564 from enteric fever, and 13 from simple and ill-defined forms of fever), and 9 from small-pox. These 14,009 deaths were equal to an annual rate of 3·1 per 1000, against 3·5, 2·6, and 2 6 in the three preceding years, 1893–4–5. Among the various sanitary areas the zymotic death-rates ranged from 1·4 in St. George Hanover-square and in City of London, 1·8 in Hampstead, 1·9 in Lee, 2 2 in Westminster and in St. James Westminster, and 2·3 in Stoke Newington, in St. Giles, and in St. Martin-in-the-Fields, to 3 9 in Chelsea, and in Woolwich, 4 0 in Limehouse, 4·2 in St. George Southwark and in Bethnal Green, 4·3 in Shoreditch, and 4·8 in St. Olave Southwark. The 9 fatal cases of small-pox registered in London during 1896 were 34 below the corrected average number in the ten preceding years; of these, 2 belonged to Lambeth and 2 to Greenwich sanitary areas. The 3692 deaths referred to measles were 900 above the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in St. James Westminster, Marylebone, Strand, Shoreditch, Bethnal Green, St. George Southwark, Woolwich, and Plumstead. The 940 fatal cases of scarlet fever were 149 below the corrected average; this disease was proportionally most fatal in St. Luke, Shoreditch, St. George-in-the-East, Mile End Old Town, St. George Southwark, St. Olave Southwark, Greenwich, and Plumstead sanitary areas. The 2663 deaths referred to diphtheria exceeded by as many as 786 the corrected average; among the various sanitary areas this disease showed the highest proportional fatality in Chelsea, Limehouse, Mile End Old Town, St. Olave Southwark, Bermondsey, Camberwell, Greenwich, Lewisham, and Plumstead. The 2931 fatal cases of whooping-cough were 232 below the corrected average; this disease was proportionally most fatal in Shoreditch, Bethnal Green, Limehouse, Poplar, St. George Southwark, St. Olave Southwark, Bermondsey, and Rotherhithe sanitary areas. The 582 deaths referred to different forms of "fever" were 82 below the corrected average; among the various sanitary areas the highest "fever" death-rates were recorded in St. Martin-in-the Fields, Clerkenwell, City of London, and Rotherhithe. The 3192 fatal cases of diarrhœa were 135 above the corrected average; this disease showed the highest proportional fatality in Fulham, Clerkenwell, St. Luke, Shoreditch, St. George-in-the-East, St. George Southwark, Newington, and St. Olave Southwark. In conclusion, it may be stated that the mortality from small-pox, scarlet fever, and "fever" was below the average, while that from each of the other zymotic diseases showed an excess.

Infant mortality in London last year, measured by the proportion of deaths under one year of age to registered births, was equal to 160 per 1000, against 164, 143, and 165 in the three preceding years. The rates of infant mortality in the various sanitary areas ranged from 123 in Hampstead, 126 in Stoke Newington, 133 in Plumstead, 136 in Lewisham, and 137 in City of London, to 180 in Shoreditch, 181 in St. George Southwark, 184 in Clerkenwell and in Newington, 193 in Strand, 194 in Holborn, and 213 in St. Saviour Southwark.



SOUTH-WEST LONDON MEDICAL SOCIETY.—A meeting of this society was held at the Town-hall, Wandsworth, on Jan. 13th, Dr. B. Duke in the chair, when a paper was read by Mr. Howard Marsh, entitled "Studies in Diagnosis, illustrated by Difficult Cases." This appeared in full in THE LANCET of Jan. 16th. A discussion followed, in which Mr. T. A. I. Howell, Mr. John Gay, Dr. Wyman, Surgeon-Major Mark Robinson, and others took part, each speaker referring to difficult cases of various kinds which had come under his observation. On the motion of the President a vote of thanks to Mr. Howard Marsh for his valuable paper was carried by acclamation.

Obituary.

EDWARD BALLARD, M.D., F.R.C.P., LOND. F.R.S.

As we announced in our issue of Jan. 23rd the death of Dr. Edward Ballard took place at his residence, Ravenscroft Park, High Barnet, on the morning of the 19th inst., at the age of seventy-six years. A few months ago he had an attack of bronchitis which tried him severely, but from this he appeared to have recovered almost completely. On the 17th inst., however, he experienced a much severer bronchitic attack, to which he rapidly succumbed. He passed peacefully away after an illness of two days' duration. Although he had suffered for some years from an ailment which kept him much at home, yet he has never given up work for a day, except when actually confined to his bed by illness. Only a week before his death a member of our staff spent an evening at his house, and on that occasion Dr. Ballard seemed bright and cheerful. He exhibited to the full his old love for statistical work and his well-known capacity of rapidly grasping the salient points of argument respecting any subject in which he took an interest. His memory seemed to be almost unimpaired, and his mental vigour was remarkable for a man of his age.

EDWARD BALLARD, M.D., F.R.C.P., F.R.S.
(From a painting by his daughter executed within a year of his death.)

Edward Ballard was born at Islington in 1820. The son of a gentleman of private means he received his early education at the Islington proprietary school, of which the head masters at that time were successively the Rev. Canon Parr and the Rev. John Jackson, afterwards Bishop of London. It was originally intended that he should take Holy Orders, but before he left school circumstances occurred which determined his selection of medicine as a profession. He was, however, to the end of his life a loyal and devout member of the Church of England, in the welfare of which he ever took the deepest interest. At the age of seventeen he was apprenticed, after the manner of the day, to Mr. Semple, who was at that time the only parochial surgeon in Islington and who was not only surgeon to the workhouse, but also a member of the staff of the National Vaccine Establishment. Mr. Semple was an enthusiastic botanist, and often accompanied his pupils into the country on botanical excursions. Under his instruction Mr. Ballard soon gained a fair knowledge of plants which was subsequently improved by attendance on the botanical classes at University College. In 1839 he entered the college as a medical student. His career at college and at the London University was a highly distinguished one. He graduated M.B. and subsequently M.D. as university medical scholar and Gold Medallist, and afterwards became a Fellow of the Royal College of Physicians. He was subsequently elected a Fellow and Tutor of University College and in 1889 a Fellow of the Royal Society.

After graduation Dr. Ballard engaged in practice, and filled the position of physician to the St. Pancras Royal Dispensary, where he had for colleagues Dr. (now Sir) Henry Pitman, the late Dr. A. P. Stewart, and the late Mr. Haynes Walton. Later he became lecturer on medicine at the Grosvenor-place School. Dr. Ballard's practical introduction to public health work was by means of his appointment as first medical officer of health to his native parish; he retained this appointment sixteen years—viz., from 1856 to the date of his promotion to office under Government. Throughout his tenure of the Islington appointment he devoted his energies to the organisation of local sanitary work and applied himself with assiduity to acquire a mastery over those branches of medical knowledge in which he subsequently achieved well-merited distinction as a teacher. It was while thus engaged that Dr. Ballard accumulated the rich fund of statistical facts concerning diarrhœa *sickness*, of which he was the first to realise the full importance and which has formed the starting point of much that he has since written on the history and behaviour of that fatal disease. Here, too, it was that he first attracted professional attention by his painstaking and skilful inquiry concerning a local prevalence of typhoid fever, which he was able to trace to a polluted milk-supply. This was the first investigation of the kind that up to that time had been made, and was perhaps as complete and successful a piece of work as any that he has since accomplished. His first important publication was a prize essay on Vaccination and its Alleged Dangers; this is a work of conspicuous merit, which has proved of great value to honest inquirers after truth in regard to this important subject. In 1871 Dr. Ballard accepted an appointment (twice previously offered him by Sir John Simon) as medical inspector under the Privy Council. On resigning his health officership in order to take up his new duties at Whitehall he was presented by the medical practitioners of Islington with a handsome microscope by Ross as a tribute of their esteem. From 1884 to 1886 he was engaged, in conjunction with Dr. Blaxall, in making a survey, for preventive purposes, of the most vulnerable points of the English coast in the not improbable contingency of cholera being imported into one or other of our ports from abroad. From that period onward to the close of his official career he was engaged during such intervals as could be spared from routine inspectorial duties in his well-known investigations into the exact nature of the disease known as summer diarrhœa. The first instalment of his report on diarrhœa was published by the Local Government Board in 1887, and ever since his retirement from office he has been engaged in further studies of the same

Hosted by Google

kind, working with unabated zeal, and for five or six hours a day, whenever his health permitted, even to within a week of his death. The only words of regret that escaped him on his death-bed had reference to the fact that this concluding report on what may be held to have been the chief study of his later years must after all be left unfinished. Several parcels of manuscript with illustrative diagrams and tables still remain as he left them; but in the interest of preventive medicine it is to be hoped that means will yet be found to preserve and render serviceable a work upon which so much valuable labour has been expended.

After his transference from the Privy Council to the Local Government Board Dr. Ballard prosecuted a series of investigations on the subject of "effluvium nuisances" arising from manufacturing processes, with especial regard to their effect upon health. The result of this investigation he presented to the Local Government Board in three successive reports, of which the high character may be gathered from the following remarks by his official chief, Sir John Simon: "The results of Dr. Ballard's study constitute a complete body of scientific and practical information for the guidance, both of the traders who produce the nuisances in question and of the authorities who ought to control them—such a body of information as is, I believe, not only without equal in its own branch of subject matter, but certainly without superior, as to thoroughness of work, in any sanitary publication known to me."

Dr. Ballard married in 1846 Julia Hannah, daughter of Mr. Charles Huggons of London. She died in 1866, leaving two sons, Edward George, now one of Her Majesty's Inspectors under the Alkali Acts; and Charles, who is now in America; also one daughter, Mary Harriet, now Mrs. Allt. As his second wife, he married Emmeline, daughter of Mr. John Halse of London. By this marriage there are two children—Robert, who at the date of his father's death was on the way to Rangoon to engage in medical practice; and Alice Emmeline.

By the death of Edward Ballard the medical profession has lost one of its brightest ornaments. A man of sterling character, and of powerful and discriminating mind, he was devoted to his profession, and was possessed of intellectual qualifications which, aided by characteristic perseverance, were a guarantee of that success in his life-work which he unquestionably achieved. He shunned popularity, and spent his life in honest and fruitful, but unobtrusive, endeavours to benefit his fellow men. Amongst the few who were admitted to the privilege of his personal friendship, his memory will be long and affectionally cherished. His remains were laid to rest on Jan. 23rd in the family grave at Woking Cemetery. We present our readers with a reproduction of a photograph of Dr. Ballard, taken from a fine portrait in oils, which was painted by his daughter Alice only a few months before her father's death.

ROBERT BEEDIE ROBERTSON, F.R.C.S. EDIN.

ROBERT BEEDIE ROBERTSON, of Ardrossan, whose death occurred on the 16th inst., was a native of Aberdeen, where he was born in 1832. He was brought up mainly in Dundee, and from the grammar school there he went to the University of Aberdeen, where he passed through a very complete arts course with distinction, and proceeded to Edinburgh to study medicine. He obtained the diploma of the Royal College of Surgeons of Edinburgh in 1859 and the Fellowship of the same body in 1862. Very early in his career he saw a great deal of country practice as assistant to the late Dr. Alexander of Wooler, in Northumberland, one of the most active medical practitioners of his day and a man of fine literary instincts and culture. But on the death of the late Dr. Houston of Ardrossan young Robertson settled there as his successor.

"Dr. Robert Beedie Robertson, of Ardrossan, Ayrshire," writes Professor Gairdner, "was one of those thoroughly skilful and devoted men who, having a very high and justly-earned local reputation as the leading practitioner of a wide district, seem not to have had the time or opportunity, or perhaps the inclination, to add in a corresponding degree to the literature of medical science. This was not in Dr. Robertson's case owing to the want of literary culture or ability, for he was an excellent Latin and English scholar and had even a romarkable power of keeping himself under the influence of contemporary thought as expressed in literature. But his professional work occupied him very thoroughly, and not being of a very robust constitution he was never tempted to spend his energies in any way that did not tend directly to the benefit of his patients. For nearly forty years he has been the trusted adviser of a very large number of the wealthier and middle classes, and has also had a large *olientèle* among the poor, whom he attended without regard to pecuniary remuneration, bestowing on them the same care as on the others, and being in regard to all classes of society the friend as well as the physician. He was also repeatedly employed in medico-legal inquiries, and had a considerable amount of consulting practice. In short, there were few men better known or more favourably known in the northern division of Ayrshire than the late Dr. Robertson."

His death followed a long and distressing illness extending over nearly three years. Probably commencing in a sudden blindness in one eye from obliteration of the central artery of the retina this illness took on the form of a cerebral affection associated with a slight, but pretty constant aphasia amounting to forgetfulness of particular, and often very familiar, words. There never was anything approaching to complete aphasia or agraphia, and there was no paralysis at any time; but although his mind remained intact and his interest in his work continued he became gradually convinced that it was necessary first to circumscribe, and afterwards to discontinue, his professional services to the public. Some time ago he formally withdrew from practice altogether and since then has been in a large measure confined to the house and often to his bed, suffering greatly from pains in the head and from occasional sudden seizures of unconsciousness. He married, in 1874, the youngest daughter of the late James Boyd of Orchard, West Kilbride, who, with two sons, survives him.

THE SERVICES.

ARMY MEDICAL STAFF.

BRIGADE-SURGEON-LIEUTENANT-COLONEL H. H. STOKES, who has been stationed at Netley for the last three years, will proceed to Singapore at an early date, for duty in the Straits Settlements. Surgeon-Major Hewett has been nominated for service in the Bombay Command, and Surgeon-Major O'Connell has been appointed to the Medical Charge of the Headquarter Staff and Establishment, Punjab Command. Surgeon-Captain H. J. Parry has assumed Medical Charge of Women and Children, Wellington Lines and Aldershot town. Brigade-Surgeon-Lieutenant-Colonel R. Harman and Surgeon-Lieutenant L. P. Tomlinson have embarked for India, and Surgeon-Captain Cree proceeds to Gibraltar.

Surgeon-Colonel Michael Cogan retires on retired pay. Brigade-Surgeon-Lieutenant-Colonel James Macartney, M.D., is placed on retired pay. Surgeon-Captain A. De C. Scanlan, from half-pay, to be Surgeon-Captain, with precedence next below G. G. Adams, vice C. C. Fleming, seconded.

INDIA AND THE INDIAN MEDICAL SERVICES.

The Governor-General has made the following appointments on his personal staff:—To be Honorary Surgeons: Surgeon-Major-General T. Walsh, A.M.S., and Surgeon-Colonel C. A. Atkins, A.M.S. Surgeon-Captain W. E. Jennings and Surgeon-Major F. F. MacCartie have respectively delivered over and received charge of the office of the Health Officer of the Port of Bombay. The services of Surgeon-Lieutenant C. D. Dawes (Bengal), are re-placed at the disposal of the Military Department.

NAVAL MEDICAL SERVICE.

The following appointments are notified:—Fleet Surgeons: William E. Breton to the *Prince George*, and Henry A. W. Richardson to the *Monarch*, afterwards to Cape of Good Hope Hospital. Staff Surgeons: Joseph H. Whelan to the *Monarch*, and to the *Penelope* when the *Monarch* becomes port guardship; Oswald Rees to the *Monarch* when commissioned; and H. S. Jackson to the *Pembroke*. Surgeons: Robert F. Bowrie to the *Tauranga* when commissioned; J. W. Craig to the *Caledonia;* William A. Whitelegge to the *Phœnix;* John H. Stenhouse to the *Algerine;* Alfred J. Pickthorn to the Portsmouth Division of Royal Marines; Ernest A. Penfold to the Plymouth Division of Royal Marines; Cyril J. Mansfield to the *Pembroke;* Hugh Clift to

Hosted by Google

the *Vivid*, additional, for Devonport Dockyard; Edward B. Pickthorn to the *Vernon*; John A. L. Campbell to the *Stork*; and James G. Towler to the *Sharpshooter*.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant David L. Anderson, 1st Banff Volunteer Artillery, to be Surgeon-Captain.

VOLUNTEER CORPS.

Royal Engineers: 1st Sussex: Surgeon-Lieutenant A. H. Croucher, M.D., to be Surgeon-Captain. *Rifle:* 2nd (Berwickshire) Volunteer Battalion the King's Own Scottish Borderers: David Robertson Dobie, M.D., to be Surgeon-Lieutenant. 2nd Volunteer Battalion the East Lancashire Regiment: Charles Edward Reading Bucknill, gent., to be Surgeon-Lieutenant.

CADET BATTALIONS.

1st Cadet Battalion the Buffs (East Kent Regiment): Acting-Surgeon C. W. Scott, M.B., resigns his appointment.

THE LATE SURGEON-MAJOR MANSER.

The esteem in which Dr. Manser, who fell a victim to the plague and a sacrifice to duty, was held in India is evidenced by the appreciative obituary notices in the Indian papers brought us this week by the mail. The *Bombay Gazette* says: "It is not too much to say that by Dr. Manser's death Western India loses a medical man of exceptional talent, and the Government a most competent and trusted medical officer."

DEATHS IN THE SERVICES.

Surgeon-Major T. W. Wilson (retired), Bengal Medical Service, on the 15th inst. at South Kensington. The deceased officer was eighty-four years of age.

Information has been received notifying the departure from the West Indies of the s.s. *Atrato*, with twelve invalids from Jamaica and Barbados for the Royal Victoria Hospital, Netley.

Brigade-Surgeon-Lieutenant-Colonel J. Arnott, M.D., has been granted a distinguished service reward of £100 per annum.

The distribution of prizes in connexion with the Volunteer Medical Staff Corps will be made at Calthorpe-street, W.C., by the Countess of Albemarle, on Saturday, Feb. 6th, at 7 A.M. The prize distribution will be followed by a dance.

BRITISH MEDICAL BENEVOLENT FUND.—The annual general meeting of subscribers to this fund was held on the 14th inst. at the residence of the treasurer, Sir W. H. Broadbent, Bart. The chair was taken by Sir James Paget, Bart., the President of the Fund. The financial statement and the report of the committee were submitted, and from them it appeared that subscriptions of £1185 9*s.* 8*d.* and donations of £365 19*s.* 6*d.*, making together £1551 9*s.* 2*d.*, had been received. The income from investments (all made according to the Trust Acts) amounted to £2086. The amount distributed in grants was £1464 15*s.*, and 107 annuitants had received £2114 6*s.* 8*d.* The distribution had been made by the honorary financial secretary through the London and County Bank, chiefly in monthly instalments, a mode which the committee find to be more and more desirable. Five new annuitants of £20 each had been elected to fill vacancies caused by death, and grants had been made to 159 applicants in sums varying from £5 to £20. Four legacies had been received during the year—viz.: from the executors of the late Mr. Tanton, £1953 6*s.* 2*d.*; from the executors of the late Dr. Fearnside, £300; from the executors of the late Mr. D. Rees Thomas, £50; and from the executors of the late Miss Hawes, £90. The last of these had, by desire of the testator, been devoted to the Grant Department. This year the accounts had been exhaustively audited by a chartered accountant and the working expenses had been satisfactorily small. The committee had received with regret the resignation of Dr. Robinson and Mr. S. G. Sloman, who had for many years acted as hon. local secretaries for Eastbourne and Farnham respectively, and who had during that time been invaluable friends to the charity. Mr. R. E. W. Brewer had undertaken the honorary local secretaryship for Newport, Monmouthshire. Votes of thanks were passed by acclamation to the treasurer and honorary secretaries, to the auditors, and to the honorary chartered accountant and to the medical press, and a very cordial vote of thanks to Sir James Paget, the chairman, for the great interest which he has always manifested in the welfare of the fund.

Correspondence.

"Audi alteram partem."

"A CENTRAL HOSPITAL BOARD FOR LONDON."

To the Editors of THE LANCET.

SIRS,—At the meeting summoned by the Charity Organisation Society on Monday it was noteworthy that, although the amendments were rejected, only a very small minority of the hundreds present voted for the original resolution. The latter was so framed that it was almost impossible to argue in favour of altering it without getting out of order. Surely every step, the earlier as well as the later ones, in forming a Central Hospital Board should be taken by a committee of representatives duly elected by the institutions concerned. At present we have a general committee of 168 individuals, who no doubt represent all kinds of excellent qualities, but who can only be said to represent the hospitals in the very limited sense in which a *sample* is representative. Organisation by pseudo-representation and semi-self-elected bodies has already done mischief enough to our hospitals. They bear the same relation to a duly elected body that an icicle does to a piece of sculpture. The former may assume a beautiful form and it may not, even when its material is absolutely clear and crystalline. At best it has no market value. Sculpture may be ugly enough, too, but if a man has modelled it himself it generally pleases him. It is of no use to tell us that "nothing is yet finally settled," that "there will be time," &c. Evil has to be checked in the inception. They can seldom be stopped afterwards. What confidence can reasonably be felt in a method of proceeding which has produced a scheme of representation with peculiarities of which the following are specimens? A general hospital of from 150 to 200 beds, if it is wise enough not to start a new medical school, is to have one representative—i. e., as many as a private house recently made into a small "hospital" for private ends. If it does start a school it will have four representatives, as many as the London Hospital with its 800 beds. A respectable hospital such as the Blackfriars Skin Hospital will have no representative. If it chose to call its large out-patient department a "dispensary" it would have one representative.

The representatives of the general practitioners are to be elected by the local branches of the British Medical Association, to which thousands of practitioners do not belong, and to which hundreds of consultants do. And so on; I only stop from fear of trespassing on your space. Why do not those who wish to see a Central Board established proceed as follows:—(*a*) Give ample notice (not five days) of a meeting at some central place—e.g., King's College; (*b*) invite the board of management and the medical staff of every hospital and public dispensary, small or great, to elect and send one representative; exclude all others from the meetings, except as reporters or spectators; (*c*) put to the meeting the simple primary question of "board" or "no board; and (*d*) if an affirmative be voted discuss schemes or a scheme of constitution for the new board—i.e., of distribution of representation. I annex what seems to me to be at least a logical one.

I think it would be time to discuss the matter with outsiders when we are agreed among ourselves. And we should then be in a position to show practically the gratitude we undoubtedly owe to Mr. Loch and his friends for taking the initiative.

I remain, Sirs, yours faithfully,

Jan. 26th, 1896. C. B. KEETLEY.

Scheme of Representation.

1. In distributing representation some simple principle should be adhered to. 2. The representation should increase with the number of beds in each hospital, the former in an arithmetical and the latter in a geometrical progression.

Hospitals with	50 beds	to have representatives	...	1
,,	,, 150 ,,	(= 50 + 50 × 2)	,,	...	...	2
,,	,, 250 ,,	(= 50 + 50 × 2^2)	,,	...	...	3
,,	,, 450 ,,	(= 50 + 50 × 2^3)	,,	...	...	4

Hospitals with less than fifty to be permitted to group themselves in their own way, one representative being given to each group with not less than fifty beds.

Dispensaries to be represented if with a certain income.

General practitioners to select their own machinery of election.

Paragraphs 2, i., ii., vi., vii., ix., and x. (pp. 6 and 7) of the Charity Organisation Society's scheme to be referred for consideration by the board as above constituted.

Hosted by Google

THE PARKE MEMORIAL FUND.

To the Editors of THE LANCET.

SIRS,—On the 13th ult. I was at the Army Medical Department, London, and in the waiting-room I noticed an appeal card for subscriptions to the above fund. The Director-General also informed me that there was a great need of further support. After leaving this office I went to Messrs. Holt and Co. of Whitehall-place, and paid in the small sum of 10*s*. They told me that Surgeon-Captain F. A. B. Daly was hon. secretary to the fund. I have to-day heard from this gentleman that a statue has been erected to the late Surgeon-Major Parke in Leinster-lawn, Dublin; that the sum of £600 has been subscribed, but that nearly £100 more is required to clear off the cost of the memorial. In THE LANCET of May 23rd, 1891, a letter appeared from Captain N. E. Stairs, headed "A Tribute to Surgeon Parke." The following week I wrote, pointing out how truly deserving Surgeon-Major Parke was of the honour of the Albert Medal. I would now take the liberty of asking those who have not already subscribed to the Parke Memorial Fund, and who would be glad to help perpetuate the memory of one of the bravest and most unselfish of our profession, to send donations to Messrs. Holt and Co., 17, Whitehall-place, London, S.W., or to myself. In either case the sums subscribed will, by the kind permission of the Editors, be acknowledged in THE LANCET. I would suggest that the amount sent by any subscriber should not be more than ten and not less than five shillings, and I would not limit this fund to only gentlemen of the medical profession. The postscript is an extract from Captain Stairs' letter in 1891.

I am, Sirs, yours faithfully,

Canterbury, Jan. 19th, 1897. PUGIN THORNTON.

"I beg of you space to insert these few lines as a small tribute to a medical man who has done his work so well and nobly. I refer to my old comrade, Dr. T. H. Parke, of the late Emin Pasha Expedition. I feel certain people have not fully realised the services of Dr. Parke to humanity. It matters nothing where or under what circumstances these services were rendered; blacks are capable of just as keen suffering and anguish as we white men are, and I therefore ask you to record the following incident, which is by far the bravest and noblest it has ever been my lot to be a witness of:—'When a portion of the Expedition was stationed at Fort Bodo, in Central Africa, Dr. Parke, who was one of the number, was seized with a violent attack of bilious remittent fever; each day he grew worse, his temperature for the whole twenty days of illness never falling below 101° F. Quinine and arsenic and all other medicines failed, and Captain Nelson and I gave up all hope of his ever recovering. He was able only to crawl slowly about his hut, and could keep nothing of the poor foods we had to give him on his stomach. In spite of this, after about fifteen days' illness, when worn away to nothing, he crept out of his hut unawares to Nelson and myself, reached the hut of a black chief, Khamis Pari, and lanced for him a large and painful abscess, cleansed and dressed the wound, and was found by Nelson and myself in an absolutely helpless condition, and carried back by us to his hut. Next day reaction set in, and both Nelson and I expected he had only but a few hours more to live. He has never spoken to any of us, or to anyone that I know, a single word of this. I think it only fair to show to his brother medical officers what one of their number has done. Those who have suffered the agonies of a heavy fever will, I feel sure, appreciate and remember this brave action on the part of Dr. Parke."

"THE HALF-YEARLY MEETING OF THE FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND."

To the Editors of THE LANCET.

SIRS,—No one will be surprised that Mr. Heath has nothing more to say about Mr. Anderson's case. What could he say when he found from my letter that the propositions he advanced so confidently—viz., that the Council of the College had twice negatived a grant in aid of the appeal to the Privy Council, that such a grant would be illegal, and that the solicitor of the College had declared it to be illegal—were at variance with facts? Nothing whatever, unless he retracted his statements—a course which I regret to think that we cannot expect from him, even when he makes public charges against individuals which are absolutely unfounded. For example, at a public meeting Mr. Heath made an entirely irrelevant attack upon my election committee for issuing a statement, and at the same time on myself for having, as a member of the Council, permitted a statement to be issued, which he regarded as reflecting on the Council of the College for its action towards me during my tenure of office on the Council. When I show that Mr. Heath's imputation is unfounded because the statement did not relate to the period of my tenure of office as a Councillor, without retracting or expressing regret for an unfounded charge Mr. Heath shifts his ground to the different and wider imputation that the statement itself is untrue. He also makes it appear as if his fresh attack sprang from my letter dealing with a part of his speech which was not reported instead of from the fact that I had made his first position untenable, thereby implying that having been deprived by the abrupt close of the meeting of the opportunity of correcting his mis-statements I might have submitted to them in silence.

Mr. Heath's second attack and so-called proof are as unfounded as the first. He states that I made my first speech on behalf of the Members in November, 1886. I beg to refer him to THE LANCET of Dec. 26th, 1885, where he will find a report of my first speech on behalf of the Members, occupying about two columns of the paper, and delivered on Dec. 17th, 1885. The speech was briefly reported in the *British Medical Journal* and inserted *in extenso* in the *Medical Times* of Dec. 19th, 1885. This is an unhappy mistake in one who goes out of his way to remove the beam which he fancies that he sees in his brother's eye and destroys Mr. Heath's so-called proof. Both from my "literary efforts" and my speeches at the College in 1885 and 1886 my advanced opinions became well-known. That such opinions and their expression at the College in direct opposition to, and criticism of, the memoranda issued by the Council were injurious to my "collegiate interests" is not open to reasonable doubt. That I was well aware of this and deliberately disregarded it at the time is shown by a passage from the very letter of Nov. 8th, 1886, to which Mr. Heath refers and which runs as follows: "From long-standing conviction and from a sense of what is due to the Members of the College and to the profession at large I have come forward again (and as I am informed and believe in opposition to my private interests) to aid a righteous and most important cause." Views such as mine, opposed to the views of those in office at the College and of the majority of the Fellows, were certain to make any other candidate (from the point of view of Mr. Heath and his friend), as Mr. Heath says, "a more eligible candidate" for office in the College than myself. From any other point of view I trust that I may be permitted, without want of modesty, to challenge comparison of my claims to the examinership with those of any who were preferred to me. Mr. Heath's reasons, however, for confining the meaning of the words "collegiate interests" to an application for an examinership are best known to himself. Perhaps he will explain them. Mr. Heath calls the Association of Fellows—a body which includes such high-minded and public-spirited gentlemen as Mr. George Pollock, Mr. Holmes, Dr. Robert Barnes, Mr. Gant, and others whom I need not mention and which publishes its proceedings—"a clique." To the action of this clique, which has been guided by the principle that the College is not for the Council only, but for the Fellows and Members as well, the Fellows and Members are indebted for many reforms and improvements at the College—the annual general meeting of Fellows and Members, the annual Report of the Council, the simplification of the system of voting papers, the common room at the College, and the half-yearly meeting of Fellows. To such a "clique" I consider it an honour to belong, and I have very little doubt that such attacks as those of Mr. Heath will impart fresh vigour to its efforts for the promotion of the best interests of the greatest of all our professional institutions.

I am, Sirs, yours truly,

Wimpole-street, W., Jan. 26th, 1897. WALTER RIVINGTON.

THE USE OF TUBERCULIN IN A DAIRY HERD.

To the Editors of THE LANCET.

SIRS,—In the *Farmer and Stockbreeder* of Jan. 11th a notice appears under this heading giving an account of the result of using tuberculin as a means of distinguishing between tuberculous and non-tuberculous cows on a dairy farm of Mr. H. Purrott, of St. Albans. It appears that 50 per cent. of the cows tested reacted to the test, and that of the cows supplied by a dealer to replace those rejected 30 per cent. were found to react to the test. It further appears that the cows originally on the farm which reacted to the test were fed off, and when slaughtered were all found to have tubercle, "but few or none in more than one organ, and not at

Hosted by Google

all in the tissue of the flesh." It is further stated that "such cows are therefore fit for human consumption, and in none of the cases, either on the farm or in those subsequently purchased, was a case of tubercle in the udder found, the essentially dangerous condition for contamination of the milk." Whilst congratulating Mr. Purrott on his pluck in seizing his cows by the tubercle, I venture to believe that the statements to which I refer merit the attention of those of us who are skilled bacteriologists. The facts that at least half of the cows on a particularly well managed dairy farm were found to be tuberculous, and that those cows were said to be apparently thriving and in good health, are worthy of consideration. The statements as to meat obtained from beasts infected with tubercle being fit for human consumption, and that it is only in cases of tubercle being found in the udder that the milk is infected, are statements about which I personally desire the opinion of the scientific pathologists. So far as my experience goes, very few dairy keepers would be willing to adopt the method which Mr. Purrott has adopted, and the practical question arises, Is it necessary or desirable that all dairy keepers should be compelled by law to take the same course?

I am, Sirs, yours faithfully,

Hatfield. LOVELL DRAGE.

LIQUID VACCINE VIRUS.

To the Editors of THE LANCET.

SIRS,—In the year 1870 Dr. Stephen Mackenzie, then resident medical officer at the London Hospital, used vaccine with glycerine in re-vaccinating the patients, nurses, and others, so that the process advocated by Dr. S. Monckton Copeman is not quite so new as supposed.

I am, Sirs, yours faithfully,

Flaxton, York, Jan. 26th, 1897. ALFRED KEBBELL.

THE LEICESTER BOARD OF GUARDIANS AND THE MIDWIVES QUESTION.

To the Editors of THE LANCET.

SIRS,—Dr. Rentoul cites the action of the Leicester board of guardians in their attempt to foist on the poor a midwife in the place of duly qualified practitioners; but this is not all the story. When the Local Government Board refused to sanction this appointment the Leicester board, after a great deal of quibbling, appointed their medical officers at half the pay promised to this L.O.S. diplomate. The uneducated woman was to receive 20*s.* where the qualified practitioner was to receive 10*s.* (it would probably have been 5*s.* if the law permitted it), so that it will be seen the board had not got the paltry excuse of economy. The Leicester board was loudly praised by the local press and the medical profession denounced in no measured terms. Why do the second-rate papers seek to magnify the virtues of quackery at the expense of education? Here we have leading articles almost daily on some new form of quackery.

I am, Sirs, yours truly,

R. BROADBENT, M.D. Edin.,

Jan. 26th, 1897. Member of the Leicester Board of Guardians.

"THE GLANDULAR FEVER OF CHILDHOOD."

To the Editors of THE LANCET.

SIRS,—I should like to express my appreciation of the admirable article by Dr. Dawson Williams in THE LANCET of Jan. 16th last. Until reading it I was totally unacquainted with Pfeiffer's writings on the subject, although for several years past I have been conversant with the complaint in question. On several occasions I have met with it in out-patient practice, and in at least two have known it epidemic amongst the members of the same household. With regard to fever, successive involvement of the glands beneath the sterno-mastoids, the freedom from definite pharyngitis or tonsillitis, and the subsequent retarded convalescence, all my cases tallied with the description given by Dr. Dawson Williams. In no one of my cases, however, was the abdominal pain sufficiently marked to call for any special examination of the abdomen, but after reading Dr. Williams's article I shall make a point of examining that region in every future case. With the name "glandular fever" I confess I am not particularly enamoured, although I am free from having any better one to suggest for the complaint. The "glandular fever of childhood," at least, I am sure is misleading, as in two cases I have known the complaint contracted by young adults when it was epidemic in their households. Dr. Donkin, too, I note by THE LANCET of Jan. 23rd, has known it occur in a young married woman. That the complaint is chiefly confined to children is indisputable; but that it is not exclusively so I feel certain. In this respect—its chief incidence in childhood—it agrees with measles, whooping-cough, and many other complaints, although no one doubts the occasional occurrence of these last in adult age. Dr. Dawson Williams's article will no doubt call forth further comments which may help to settle some of the doubtful points in the disorder.

I am, Sirs, yours faithfully,

Upper Berkeley-street, Jan. 24th, 1897. J. A. COUTTS.

"THE ASSOCIATION OF GALL-STONES WITH DERANGEMENTS OF THE PANCREAS."

To the Editors of THE LANCET.

SIRS,—The case recorded by Dr. Morton of Pancreatic Cyst associated with Gall-stones in THE LANCET of Jan. 23rd interests me very much. In the *British Medical Journal* of Nov. 14th I recorded a case which I judged to be one of acute pancreatitis in which the pancreatic disease was associated with gall-stone. One gall-stone was found post mortem projecting into the duodenum. I ventured to suggest that possibly the gall-stone may have furnished the necessary abrasion of surface for the entrance of micro-organisms to the adjacent pancreas. Since recording that case I noticed in the description of the Pathology of the Pancreas by Ziegler (translated by Dr. MacAlister) a case is referred to, recorded by Chiari, of suppurative pancreatitis associated with gall-stones. The relation between the acute and chronic diseases of the pancreas has yet to be determined.

I am, Sirs, yours faithfully,

R. H. KENNAN.

City Hospital, Park-hill, Dingle, Liverpool, Jan. 23rd, 1897.

THE MOSQUITO AS A VEHICLE OF INFECTION.

To the Editors of THE LANCET.

SIRS,—Professor Bignami's hypothesis of mosquitoes carrying malarial infection from one person to another is surely not intended to be taken seriously. If it were true every European in India would be attacked sooner or later, and yet how very few European women ever suffer from malaria. For more than the past year I have been taking very careful notes of all malarial cases admitted into the Royapettah Hospital, and in no instance has an intern patient developed malarial fever in the hospital. My hospital contains fifty beds, and all sorts of cases, medical and surgical (excepting obstetrical), are admitted. The hospital is only an old dwelling house, the sanitary surroundings are execrable, and it is for a hospital about as badly constructed as could be imagined. The neighbourhood abounds in mosquitoes, chiefly the grey or brown variety, and I have counted as many as 102 on the outside of a patient's mosquito net in the morning.

Next to a case of summer-autumn or winter-spring fever may be found a case of fractured femur: the latter will certainly remain in the hospital more or less helpless for a month, and if mosquitoes have the power of inoculating malarial fever, surely a case of protracted residence in the hospital would sooner or later contract the disease. I have had and kept mosquitoes, after a good feed, over nine days in captivity, and under less artificial restrictions they would probably live longer. As mosquitoes are not given to travel much, one which had sucked the blood of a malarial patient would have ample opportunity of inoculating other patients; but, as I have said before, I can recall no case. New-comers to India, whose blood is much sought after by mosquitoes, do not appear to suffer more from malaria than old residents. That malaria can be imported into a district seems proved by the history of the islands of Réunion and Mauritius. Recently the inhabitants of some villages to

Hosted by Google

the north of Madras petitioned the Government on account of a very bad type of malarial fever which was decimating their dwellings. They said that fever was unknown until about two years ago, when a family suffering from malaria came from Cuddapah—a most malarious place—and since then fever had been rife. Several of the villagers have come to my hospital for treatment, and in all crescents were found in their blood.

Professor Bignami would contend that these people had been inoculated by mosquitoes, but I think that most medical officers in India would maintain that the drinking water had been contaminated in some way. Dr. Manson's theory is a very plausible one, and, judging from the analogy of filaria, it ought to be the correct explanation. I much prefer to believe in the mosquito infecting the water-supply than in its inoculating individuals.—I am, Sirs, yours faithfully,

A. J. STURMER, Surgeon-Lieutenant-Colonel.

Madras, Jan. 7th, 1897.

A CONFERENCE OF GENERAL PRACTITIONERS.

To the Editors of THE LANCET.

SIRS,—Surely the time has come when some united action should be taken by the whole body of general practitioners of the United Kingdom with a view of checking the present downward tendencies of our profession, and with this object in contemplation I would suggest that this year should mark a fresh epoch in the corporate life of the medical profession, not only in reference to ourselves, but to the public. In short, we might with advantage follow the example of other bodies of men (trades unions and others) in combining together in order to protect our own interests, and I take it that in order to accomplish this such a conference as I propose should be convened in London at some suitable time and place. And the same might be held under the presidency of our three newly-elected representatives on the General Medical Council. There should be no difficulty in obtaining delegates to attend such conference, and I think none of us will deny there is any lack of subjects now ripe for discussion, &c. Should this suggestion meet with approval, I shall be glad to hear from any brother practitioner willing to assist in this forward movement, stating at the same time in writing the particular subjects which in his opinion, and having regard to his own particular district, should form the basis of discussion by such conference.

I am, Sirs, your obedient servant,

T. HOWARD BROCKLEHURST, M.R.C.S. Eng., &c.

Weymouth, Jan. 25th, 1897.

*** We do not think that the profession would gain much from such a conference if instituted. As an expression of wide dissatisfaction it would be behind the times, for no one denies that the medical profession has many and various grievances; but as a method of relieving them a conference would lead to but little. Who is to decide which are local, petty, and personal grievances, and which are the questions that seriously affect the profession?—ED. L.

"ARMY EXAMINATIONS."

To the Editors of THE LANCET.

SIRS,—Your correspondent "Physician"[1] is apparently anxious to support the crammers, and yet his letter contains ample confirmation of everything that was stated in the annotation which he qualifies as "open to much criticism." To begin with, he says, "The fact is that in our large public schools the special education required interferes greatly with the general school studies." Precisely so; that is exactly what the correspondents whose letters you alluded to, complain of. But surely "Physician" would not have us believe that the system of education obtaining in our public schools is a bad one. That Waterloo was won in the playing fields of Eton and Harrow is a saying which may or may not have been uttered by Wellington, but in my humble opinion there is a great deal of truth in it. I firmly maintain, in common with most Englishmen, that our public schools are the best in the world and that in no other educational establishments can young fellows be turned out so well fitted in every respect for positions of responsibility in the army or any other walk of life. An examination that favours the withdrawal of boys from school before the usual time must be radically wrong, and therefore the sooner the present portal of entrance to Her Majesty's service is made less crooked the better it will be for all concerned. Your correspondent next tells us that "the duller, and lazier, and ill-prepared ones [schoolboys] ..... are taken in hand by special instructors, whom it is a gross injustice to stigmatise as 'crammers.'" Surely he must now see that this is in direct accordance with the spirit of your remarks. Thirdly, "Physician" asserts that crammers are men who "by force of character and experience, by careful study of each individual, and with the assistance of a staff of highly-trained assistants, succeed by genuine solid work in many instances where schoolmasters have failed." Does he mean to imply that the head masters of our great schools are deficient in all these respects? If so, I can only wonder at his adoption of such a singular line of argument. Incidentally "Physician" observes that Lord Wolseley and Lord Roberts would have been eliminated if physique had been a leading feature, but there also I am quite unable to agree with him. Both of these distinguished officers are men of exceptionally good physique, on a small scale it may be, but essentially sound and capable of enduring the trials and vicissitudes of a soldier's life. It would be easy to still further dissect your correspondent's letter, but the foregoing will suffice. Truly in this case the crammers have a right to pray for deliverance from their friends!

I am, Sirs, yours faithfully,

Jan. 16th, 1897. UNCRAMMED.

[1] THE LANCET, Jan. 16th, 1897, p. 209.

"POST-PARTUM HÆMORRHAGE AND ITS TREATMENT."

To the Editors of THE LANCET.

SIRS,—In reply to Mr. Stanmore Bishop's comments on my query as to the use of Davy's lever, may I be allowed to say I think it would be impossible to make effectual manual compression of the aorta in very stout women, even disregarding the obstacle presented by the state of the uterus? Absence of an instrument does not preclude the use of the hand.

I am, Sirs, yours faithfully,

Jan. 20th, 1897. RINALDO.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Liverpool Northern Hospital.

THE annual meeting of the subscribers to this hospital was held on the 20th inst. at the town hall, under the presidency of the Lord Mayor. The committee in their report stated that during 1896 there had been 1573 in-patients and 5630 out-patients. The ordinary expenditure had been £6519, against £6643 in 1895. The adverse balance of £4019 at the end of 1895 had been wiped out by a transfer from the special fund of £4000 raised in response to the committee's appeal. Independently of contributions to that fund the receipts for 1896 had been £5715 15*s.* 7*d.* The adverse balance of last year incurred in working the ambulance had been generously paid off by Mr. Walter Holland. Thanks were expressed to Mr. L. S. Cohen, who had presented the new horse ambulance carriage, a description of which appeared in THE LANCET. The report added that the convalescent fund continued to be of great assistance in hastening the recovery of patients; that the nursing institution in Paisley-street had proved of increasing value to the hospital and to the general public; and that the committee gfatefully acknowledged the donation of £1430 from the Hospital Sunday and Saturday Funds. In concluding they thanked the public for their response to the appeal for funds for the furnishing and maintenance of the New David Lewis Hospital; £31,400 had been contributed for this purpose, and it was hoped that the remaining £8600 would be obtained as soon as possible. A pleasing feature of the report was the statement that the David Lewis trustees had increased their contribution towards re-building the hospital from £60,000 to £80,000.

Birkenhead Borough Hospital.

The committee's annual report stated that the improved

Hosted by Google

financial position referred to in the report for 1895 had been more than maintained. This result was in no small degree due to the pecuniary aid afforded through the "Employés" Fund," from which they received a sum of £1095 1*s.* 11*d.* The subscription list had reached £1015 10*s.* 6*d.*, and the total income from all sources was £3720 7*s.* 10*d.* The expenditure included considerable items over the ordinary outlay for structural additions and alterations. The patients treated in the hospital during the year numbered 11,139, which was the largest number yet recorded. Of these 726 were in-patients, against 674 in 1895. These figures pointed to the need of extending the accommodation at an early date, and the committee desired to increase the reserve fund with that object. In October a horse ambulance carriage was provided for the town through the medium of the St. John Ambulance Association. It was manned and horsed from the municipal fire station and had proved a most valuable acquisition. The Mayor, on moving the adoption of the report, said it was a most gratifying circumstance to find such a substantial sum contributed by the working men of the town, but regretted that the general subscriptions had not increased in the ratio they might have expected.

Liverpool Medical Institution.

The report of the Council for the year 1896 shows that thirteeen new members and eight associates were elected during the year; two associates have become members. Tne list of members and associates numbered 283, compared with 286 at the same period of 1895. The average attendances at the ordinary meetings (which are held fortnightly from October to the end of April) were 77, and at the meetings of the Pathological and Microscopical section 46. At the ordinary meeting held on March 26th last, when Professor Lodge gave a demonstration of the Roentgen radiography, there were present 200 members, associates, and visitors. The number of books in the library were 10,461, an increase of 128. The expenditure during the year, which was above the average owing to the purchase of a number of microscopes and appliances, and to the erection of a handsome porch in the hall designed by Professor Simpson of University College, Liverpool, amounted to £612 11*s.* 10*d.*, leaving a balance of £132 15*s.* 10*d.* The oldest member is Dr. John Cameron, senior physician to the Royal Southern Hospital, who was elected in 1839. Dr. J. Birkbeck Nevins, the next senior on the list of members, was elected in 1844, and filled the office of President in 1886-87; the same post was held by Dr. Cameron in 1872-73. The society includes one lady member, Miss Lucy Cradock, the medical attendant to the female clerks in the Liverpool post-office.

The "Black Draught" Fatality in Liverpool.

An inquest recently held by the Liverpool coroner touching the death of a corporation pensioner, to whom a lad of sixteen years of age, an assistant in a druggist's shop, sold a quantity of laudanum in mistake for a "black draught," shows the absolute necessity of keeping all poisons apart from other drugs. It can hardly be credited that laudanum and black draught, which are so much alike in colour, would be kept in such close proximity as was proved to be the case in this instance. The boy Jennings stated in his evidence that the black draught bottle was kept on a shelf immediately below that on which the laudanum bottle was stored, the two bottles also being of the same size. The fact of the boy being in a hurry at the time he made the fatal mistake emphasises the danger of placing poisonous compounds so near each other. Another danger to the public consists in laudanum not coming under the class of "dangerous poisons" as sworn to by the manager of the shop referred to. The coroner, in summing up, said that the juxtaposition of the bottles was a remarkable circumstance in the case, and he was strongly of opinion that bottles containing poison, whether of an ordinary or extraordinary nature, should be kept in a separate part of the shop and should be of a distinctive make—a remark which was emphatically endorsed by the jury on returning their verdict of accidental death.

Further Demolition of Insanitary Property.

The fourteenth presentment of insanitary property was made to the grand jury at the City Quarter Sessions on Tuesday. The presentment included 890 insanitary houses in Toxteth-park and in the centre of the city. To carry out their scheme the Insanitary Property Committee of the city council obtained from the Local Government Board permission to borrow £50,000.

Port Sanitary and Hospitals Committee.

The estimates of the Port Sanitary and Hospitals Committee for 1897 amounted to £27,899 ordinary expenditure and to £2325 capital expenditure.

Jan. 26th.

WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The Proposed Sanatorium for Bristol.

UNDER the presidency of the Mayor a meeting was held on Jan. 20th to consider the best means of celebrating in Bristol the completion of the sixtieth year of the Queen's reign. A communication was read from the governing bodies of the Infirmary and General Hospital drawing attention to the importance of providing a convalescent home, and mentioning that one advantage would be that beds vacated by patients sent to it would be available in cases of emergency, whereas at present it was sometimes found necessary to refuse patients at these institutions. The sanatorium scheme was received very favourably, one gentleman offering a large house at the corner of Durdham Down for this purpose, and two offers of £2000 each were made subject to the proposal for a convalescent home being adopted. The meeting was adjourned, and at the next, Mr. J. S. Fry will move a resolution in favour of a sanatorium, and that at least a sum of £40,000 should be raised of which at least one half would be required for the endowment fund.

Health of Bristol.

At the meeting of the Bristol Sanitary Committee held on Jan. 14th the medical officer of health (Dr. D. S. Davies) reported that during 1896 the birth-rate in Bristol was 27 8, compared with the birth-rate of the thirty-three large towns of 31·3. The death-rate was 16·8, compared with 19·6 of the thirty-three large towns. Both the birth- and death-rate for 1896 gave the lowest figures he could find recorded for the city. The infant mortality was 138 per 1000 births, compared with 168·3 in the large towns. The year had been marked by no very unusual prevalence of epidemic disease, except that scarlet fever prevailed in a somewhat mild form; forty-four cases of small-pox appeared in the city and surrounding districts during the first half of the year. A somewhat large number of cases of diphtheria was notified, but the fatality was about the average of the last five years. Enteric fever had at no time prevailed in other than sporadic form, and the deaths were below those recorded during either of the three previous years.

Death of Albert George Cunningham, M.B., C.M. Aberd.

Dr. Albert George Cunningham, of Wellington House, Bristol, committed suicide by taking prussic acid on Jan. 17th. At the coroner's inquest a verdict of "suicide whilst temporary insane" was returned. Dr. Cunningham received his medical education at the Bristol Medical School and the University of Aberdeen; he graduated M.B. and C.M. of that University in 1882. The deceased had an extensive practice in Bristol, and took a great interest in municipal affairs, being a member of the town council for three years. He was honorary surgeon-accoucheur to the Bristol Lying-in Institution. The funeral took place at Greenbank Cemetery on Jan. 23rd.

Bristol Naturalists' Society.

The thirty-fourth annual meeting of this society was held on Jan. 14th at University College, Bristol. Professor Sidney Young, F.R.S., presided. The secretary stated that there was a slight increase of members. Mr. S. H. Swayne, M.R.C.S.Eng., was elected president. Professor Young gave an interesting address upon Crystals.

Libel Action by a Medical Man at Tenby.

At the Pembrokeshire Assizes, held on Jan. 18th, Mr. D. A. Reid, M.D.Edin., M.R.C.S.Eng., brought an action for libel against the proprietor and managing editor of the *Tenby Observer*, and claimed damages in respect of two paragraphs which appeared in the defendant's newspaper. It appeared that Dr. Reid, who had practised in Tenby for twenty years, was in attendance upon a patient suffering from small-pox at Penally. Shortly afterwards the

Hosted by Google

Tenby Observer contained a paragraph which stated that "through the ignorance and stupidity of a local professional man Tenby has narrowly escaped a serious disaster," and a warning was given to the person referred to that a repetition of his negligence will mean ruin to himself as well as loss to the public generally. There was also another very similar paragraph in a later issue. The counsel for the defendants, after a consultation, stated that his clients were prepared to withdraw all imputations made and to consent to a judgment against them for £100 and costs; he added that the defendants extremely regretted what had been published and withdrew any reflection on the professional ability of the plaintiff, and they promised not to further attack him in his personal or professional character. Judgment was then entered on these terms.

Crime in Cardiff.

At the meeting of the Cardiff corporation watch committee held on Jan. 13th the head constable presented his annual report, which showed that during 1896 the number of persons proceeded against summarily was 6657 (being an increase of 442 since 1895), 3611 were convicted, 2935 discharged, and 206 were proceeded against on indictment. For drunkenness 1635 persons were prosecuted, as against 1464 in the preceding year; 594 were convicted and 1041 discharged. For the illegal sale of alcoholic liquor 106 persons were prosecuted (a decrease of 90 on 1895) and 85 were convicted.

Health of Cardiff.

Dr. Walford, the medical officer of health for Cardiff, reported to the Health Committee of the county borough on Jan. 12th that 5591 births (equal to a rate of 34·3 per 1000) and 2795 deaths (equal to 17·1 per 1000) had been registered during 1896. The death-rate was the lowest, with the exception of 1895 (when it was 16·2) since the statistics were first compiled in 1845. The zymotic rate of mortality was 2·2; 923 deaths occurred in children under one year and 464 deaths were in persons aged sixty and upwards. Small-pox caused 3 deaths.

Cardiff Infirmary.

At the monthly meeting of the Cardiff Infirmary Committee, held on Jan. 13th, under the presidency of Dr. W. T. Edwards, it was stated that a cheque for £3300 had been sent to the building fund of the infirmary as a result of the recent bazaar; the Marquis of Bute had forwarded £1000, Mr. Forrest 50 guineas, and Mr. Cory and Dr. Edwards had collected £1127 for the same object. It was suggested as a means of celebrating the "Queen's Diamond Jubilee" that a sum of £1000 should be raised with which to endow a cot in the children's ward, to be called the "Royal Victoria Cot." The idea was warmly taken up and a sub-committee was appointed to carry it into effect.

Pembroke Dock Water and Drainage.

At a meeting of the Pembroke Town Council, held on Jan. 11th, it was resolved to apply to the Local Government Board for sanction to borrow £27,000 for water-supply purposes and a sum of £15,000 for drainage.

The Gloucestershire County Council.

At the quarterly meeting of the Gloucestershire county council, held on Jan. 11th, the chairman (Sir J. E. Dorington) said that the council would have to fill the vacancy caused by the retirement of Dr. Ancrum from the aldermanic bench. Dr. Ancrum had rendered such long and excellent service to the county that he had asked him whether he had any wish in the matter of his successor and Dr. Ancrum had mentioned a name (that of Sir W. Guise, Bart.) which quite coincided with the policy of the council heretofore. Eventually this gentleman was elected.

Lunacy in Gloucestershire.

The report of the visitors of the lunatic asylums presented at the recent meeting of the county council stated that there had been a diminution in the number of insane poor admitted from the unions in the county, as shown by the admissions of the past four years: 1893, 279; 1894, 324; 1895, 315; 1896, 286. The cost to the county for maintenance was 7*s.* 10*d.* per head per week for the first quarter, and 7*s.* 7*d.* for the remaining three. This included the clothing of the patients, salaries of officials, and the uniform and wages of the attendants. This rate of maintenance is 1*s.* 3*d.* a week below the average of the other asylums of England and Wales. The visitors recommended a grant of £1500 for their farm and this was agreed to by the council.

The Wells Dispensary.

The annual meeting of this institution was held on Jan. 14th under the presidency of the Rev. Prebendary Beresford. The hon. secretary reported a balance in hand of only £7 6*s.* Some discussion took place upon the critical position of the institution, and it was resolved to make a special effort to increase the subscription list and to continue to carry on the dispensary on its present basis.

Jan. 27th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh Royal Infirmary.

A MEETING of contributors to the Edinburgh Royal Infirmary was held last week to receive the report of the committee of contributors upon the annual report of the managers. After dealing with the finances of the institution the report went on to consider various questions in which members of the profession took a very active interest. The first of these had reference to the new laundry being placed in Lauriston-lane. Dr. Batty Tuke had strongly opposed this at the preceding meeting of contributors. The committee, however, upheld the decision of the managers and considered that they had adopted the wisest course under the circumstances. The next matter dealt with was the new set of rules which had been approved of by the managers. The committee suggested that the rule which provided that if any member of the medical staff accepted the office of a manager he should *ipso facto* be held to have demitted his appointment should be deleted. The question is one which has given rise to a good deal of feeling in certain circles, some of the staff feeling strongly that they ought not to be debarred in this way from sitting on the board, while many of the lay managers held that the medical element was strongly enough represented on the board, seeing that the University, the Royal College of Physicians, and the Royal College of Surgeons each sent two members to the board, seven of whom were medical men. The question was again discussed at this meeting with the result that the recommendation of the committee was carried by 28 votes to 22. Another question referred to was the supervision of nurses. At present the lady superintendent has power to dismiss nurses with the sanction of the general superintendent, but it had been thought that there should be an appeal to the managers, and the committee had confirmed that. The report further expressed satisfaction with the general management of the institution, and stated that the floor-space was 149 feet per bed, which was unsurpassed except in the case of the city hospital of Antwerp.

Edinburgh University Court.

At the last meeting of this court the following additional examiners were appointed in Medicine:—Dr. R. Bruce Low, London, in Forensic Medicine and Public Health; Mr. Robert Turnbull, B.Sc., Edinburgh, Botany; Dr. De Burgh Birch, Yorkshire College, Leeds, Physiology; Dr. Gibson, Edinburgh, Medicine; Dr. Haig Ferguson, Edinburgh, Midwifery.

Longmore Hospital, Edinburgh.

The report of this useful institution, which is a hospital for incurables, has been issued. The result of the last additions to the building was that accommodation was now provided for 110 patients. In the course of last year the committee decided to still further enlarge the hospital by the addition of a new wing specially designed for cases of phthisis and cancer. Buildings had also been decided upon for new laundries and for an increase in the domestic offices. There had been an increase both in the annual subscriptions and in the donations and legacies received during the year.

The Jubilee of Anæsthetic Midwifery.

On Jan. 19th Professor Simpson of Edinburgh delivered a special lecture to his midwifery class on the career of his predecessor in the chair, Sir James Y. Simpson. The lecture was in recognition of the jubilee of anæsthesia in midwifery practice, for it was that day in the year 1847 that Sir James had first given an anæsthetic to a midwifery patient. The lecturer very fairly and fully discussed the part Simpson took in the introduction of chloroform.

Glasgow University.

The following appointments to examinerships are intimated:—In Medicine, Mr. Guthrie Rankin, M.D. Glasg.,

Hosted by Google

London; in Surgery, Mr. J. A. Adams, M.D. Glasg., surgeon to the Glasgow Royal Infirmary; in Pathology, Mr. T. K. Monro, M.D. Glasg., assistant physician, Glasgow Royal Infirmary; and in Physiology, Mr. W. Stirling, M.D., D.Sc. Edin., Professor of Physiology in Owens College, Manchester. Mr. C. Workman, M.D. R.U.I., Lecturer on Pathology in Queen Margaret College, has also been appointed to be an examiner in Pathology. Professor Joseph Coats has presented to the University various instruments and apparatus for the equipment of the Pathological Laboratory, and the University Court has acknowledged the gift. The Court has appointed Dr. Robert Perry to be a director of the Glasgow Samaritan Hospital for Women. Plans for the new engineering and botanical laboratories have been finally adopted. The present arrangements for the teaching of Public Health in the University being regarded as unsatisfactory a joint meeting of the Court and Senate has been called to formulate a more complete scheme.

Anderson's College Medical School.

Dr. J. Pearson Munro has resigned his position as lecturer on Public Health in this school on account of ill-health. He has been presented on his retirement with a purse of sovereigns by his friends and former students. There is also a vacancy in the chair of Botany.

Western Infirmary, Glasgow.

Professor Murdoch Cameron and Dr. W. L. Reid have retired from their positions as physicians in the out-door department for diseases of women. They both remain in the service of the hospital in charge of the wards for the treatment of diseases of women and as clinical teachers. For the vacancies in the junior staff there are a number of candidates already in the field.

St. Andrews and Dundee.

A recent decision of the Privy Council would appear at last to have put in the way of settlement the long and complicated quarrel between the University of St. Andrews and Dundee College. The ordinances approved by the Privy Council practically settle the union of the two colleges on the lines originally drawn by the Scottish Universities Commission, but remove the Dundee representatives from the University Court of St. Andrews, and on the other hand leave the Dundee College to manage its own internal affairs. It is still permitted to conduct Arts classes at Dundee, and these are to qualify for graduation. There can, however, be little doubt that the main function for Dundee is to provide faculties in science and medicine, and it is to be hoped that the two institutions will now cease their squabbling and each devote itself to the prosecution of that particular portion of University work for which it is naturally best fitted.

Glasgow Philosophical Society.

At a recent meeting of this society a paper on "The Vaccination Commission's Report: a Plea for Re-vaccination," was read by Dr. J. C. McVail, medical officer of health for the counties of Stirling and Dumbartonshire.

Glasgow Microscopical Society.

The January meeting of this society was occupied by a lecture and demonstration on the Central Canal of the Brain and Spinal Cord by Dr. Alexander Macphail, Demonstrator of Anatomy in the University of Glasgow. Dr. Macphail showed a large number of diagrams and microscopical preparations and was awarded a vote of thanks on the proposal of Mr. J. Rankin, B.Sc.

Aberdeen Royal Infirmary.

The directors of the Royal Infirmary, Aberdeen, having requested that noiseless pavement should be laid in the streets adjoining the infirmary the town council has resolved to lay the roadway of Spa-street with tar macadam. The case of Woolman-hill, the street on the other side of the hospital, cannot yet be settled.

Jan. 27th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Longevity in Ireland.

THE vesy interesting leading article on longevity in THE LANCET of Jan. 9th has served to remind me that some remarkable cases of very old age have recently been chronicled in Ireland. Mrs. Margaret Hobbs, of Barnaboy House, King's County, recently deceased, was born on July 18th, 1794, and was, therefore, when she died in her 103rd year. According to the King's County correspondent of the *Freeman's Journal* she remembered, when she was a young woman, the celebration of the jubilee of George III. She was the wife of Thomas Hobbs, J.P., Captain in the 92nd Highlanders, who was severely wounded in action at Quatre Bras. Her Gracious Majesty took a kindly interest in Mrs. Hobbs and sent her many Royal messages of congratulation. On July 18th last Her Majesty's message said that she was "conscious of the touching fact that to-day you attain the great age of 102 years." Her Majesty further alluded to the brilliant military services rendered by Mrs. Hobbs's deceased husband and family, and expressed "the earnest hope that the military instinct that has been so marked in the past and present may be equally developed in the future history of the family." Mrs. Hobbs was the last or one of the last survivers of the widows of officers who fought at Waterloo, and was herself long ago a friend and correspondent of the great Duke of Wellington. Mr. Congreve Rogers of Tramore died last month. He was an old sportsman and follower of the famous Faithlegg Hounds in Waterford. He died at an age which has been variously estimated at from 104 to 107.

Sending Hydrophobia Cases for Treatment to Unqualified Persons.

At a meeting of the Newry board of guardians on the 23rd inst. the clerk announced that the board's solicitor had been served with a writ at the suit of the Local Government Board against the guardians, to have refunded to the rates the sum of £21 6*s*., paid by the guardians on foot of a decree obtained against them by Philip McGovern, Cowan, for the treatment of four persons bitten by a rabid dog. The guardians decided to defend the case and authorised their solicitor to employ counsel for that purpose. The result of this case will be awaited with interest, inasmuch as the decision arrived at will form a precedent, and will probably settle once for all the law in reference to the employment of unqualified persons by boards of guardians.

The Jubilee of Queen's College, Belfast.

The past week in college and medical circles in Belfast has been a most interesting and busy one, owing to the opening of the new Students' Union by the Lord-Lieutenant of Ireland, the celebration of the Jubilee of the Queen's College, the visits of Lord Kelvin (a Belfast man and former professor at the old Academical Institution) and of Lord Lister. The proceedings began on Jan. 19th, when, at three o'clock in the afternoon, the Lord-Lieutenant and the Countess Cadogan, accompanied by their host and hostess (the Marquis and Marchioness of Londonderry) and a large house party from Mountstewart, among whom were the Marquis of Dufferin and Ava, the Marchioness, Lady Hermione Blackwood, Lord Castlereagh, and Colonel Saunderson, M.P., arrived at the New Union Buildings. Here they were received by the President (Dr. Hamilton) and the professors of the College, and, having been presented with a gold key, the Lord-Lieutenant declared the Students' Union open. This beautiful building, with its reading-room, debating-hall, dining-room, refreshment and recreation room, has been opened free from debt, at a cost of £8000, subscribed for by friends of the College, professors, graduates, and the general public. The viceregal party were conducted through the new physiological and pathological laboratories, which Earl Cadogan declared open, and over which they were shown by Professor Thompson and Dr. Lorrain Smith, and they then proceeded to the library, which was crowded by students, professors, and those interested in the Union. The President then made a short and interesting statement, giving an account of the rise and progress of the College and of its former distinguished professors and graduates. A vote of thanks, on the motion of the Right Hon. Thomas Sinclair, M.A., D.L., seconded by Dr. Redfern, was most cordially passed to the Lord-Lieutenant, and the audience present adjourned to the great hall, where a very brilliant reception, attended by over 800 people of Belfast and Ulster, was given by the President and professors of the College. On Wednesday, Jan. 20th, the graduates' dinner took place in the great hall of the College, when nearly 300 gentlemen were present, including the President of the College (who occupied the chair), the professors and lecturers, and graduates, and a large number of

Hosted by Google

guests, amongst whom were the Lord-Lieutenant of Ireland (Earl Cadogan), the Marquis of Dufferin and Ava, the Marquis of Londonderry, Lord Kelvin, Lord Roberts, Sir Thomas Moffett (President of Queen's College, Galway), the Moderator of the General Assembly, the Lord Bishop of Down, Connor and Dromore, Dr. Meredith and Dr. McGrath (secretaries of the Royal University of Ireland), the Lord Mayor of Belfast, Professor Fitzgerald, T.C.D., Mr. J. B. Dogherty, M A. (an old Belfast student), Under-Secretary to the Lord-Lieutenant, the Right Hon. Thomas Sinclair, M.A., Mr. Arnold Foster, M.P., Sir James Haslett, M.P., and Sir Samuel Black (Town Clerk). The following were the toasts:—"The Queen," proposed by the President; "The Prince and Princess of Wales and the other members of the Royal Family," proposed by the President; "The Lord-Lieutenant and Prosperity to Ireland," proposed by the President, to which Earl Cadogan responded; "The Army, Navy, and Reserve Forces," proposed by the Right Hon. Thomas Sinclair, M.A., D.L., to which Field-Marshal Lord Roberts replied; "Queen's College, Belfast," proposed by the Marquis of Dufferin and Ava, to which the President, Professor Purser, and Professor Cumming, M.D.R.U.I., replied; "Other Colleges and Learned Bodies," proposed by Professor Park, to which Lord Kelvin, Sir Thomas Moffett, and Professor Fitzgerald, T.C.D., replied; "The City and Trade of Belfast," proposed by Mr. J. B. Dogherty, to which the Lord Mayor (Mr. Pirrie) and the President of the Chamber of Commerce (the Marquis of Londonderry) replied. The banquet was in every respect a great success and a most pleasant *réunion* of old Belfast graduates. On Thursday, Jan. 21st, a reception was given by the Executive Committee of the Students' Union in the new buildings, which was specially attended by the students and graduates. Most of the professors and a large number of the public were also present. The President of the College gave a short account of the origin and progress of the Students' Union. He welcomed very warmly the students there that night, thanked them for their admirable behaviour during the jubilee celebrations, and hoped they would spend many happy hours in the new buildings. He announced that on Monday, Jan. 25th, everything would be ready in the various rooms for the members of the Students' Union. A well-selected and popular programme of music was then gone through, and a very pleasant evening was spent by all those present. On Friday, Jan. 22nd, the jubilee proceedings came to a conclusion, when the Lady Mayoress unveiled a portrait of Rev. G. Hill, to be placed in the great hall of the College. Mr. Hill had been for thirty years librarian of the College. In the evening the students of the union committee held a reception, which was largely attended.

Jan. 26th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Widal's Reaction for the Diagnosis of Enteric Fever.

PROFESSOR FRAENKEL of Halle, a former assistant to Professor Koch, has published an article in the *Deutsche Medicinische Wochenschrift* on the results obtained by Widal's reaction for the diagnosis of enteric fever. The details of the process have been already described by various writers in THE LANCET. In Germany the first confirmation of Widal's discovery was a paper in the *Berliner Klinische Wochenschrift* by Dr. Breuer, of Königsberg, who examined forty-three cases of enteric fever and found the reaction to be present in every instance, whilst it failed in the serum of twenty-seven patients suffering from other diseases. Only some cases, where bacteria coli were present in great masses, were found to influence the bouillon in a way similar to the agglutination typical of enteric fever; the fluid became cloudy for a few hours, but very soon regained its normal appearance. Dr. Breuer's patients were in various stages from the sixth day to the sixth week of the illness. He also examined the blood serum of nine convalescents; two of them, who had been free from fever for seventeen and twenty-four days respectively, yielded a negative result, but the reaction was obtained with the others. Owing to the rarity of enteric fever in Germany Professor Fränkel was in the month of August able to examine only one patient in the University Hospital of Halle; the reaction in this case was thoroughly typical, and in the middle of December, owing to the outbreak of an epidemic in the village of Almrich, he had ample opportunity for continuing his researches. He modified Widal's procedure by puncturing the finger tip with a sterilised lancet and collecting from 1 to 1½ c.c. of blood, which was then transferred to a sterilised glass tube. The coagulation of this blood yielded about half a cubic centimetre of serum, one or two drops of which were then mixed with a bouillon culture of enteric fever bacilli, and a hanging drop of this mixture was examined microscopically. It could then be decided at once whether the case was enteric fever or not, for if the reaction failed the enteric fever bacilli moved about as usual across the field of view, but if the reaction took effect they became as it were paralysed. At the margin of the preparation there was no material change in the distribution of the bacilli, but in the middle they became agglutinated in lumps. After some time they showed distinct symptoms of degeneration, their outlines losing their sharpness and their substance assuming a granular appearance. Professor Fränkel points out that the influence of the enteric fever serum on the cultures is more obvious on microscopical examination than when the result is inferred from the appearances presented in the glass-tube. With respect to this modification of the test he could only confirm the observations of Widal, Breuer, &c. The alteration of the culture was, according to his observations, most pronounced from twelve to fourteen hours after it had been mixed with the serum. Professor Fränkel examined the serum of twenty-eight patients, seven of whom were still confined to bed, and two of whom had been respectively two and three days without fever. With all these patients the serum showed a very distinct reaction. One of the patients had been ill for only two days; with the others the duration of the illness varied from fifteen days to six weeks, reckoning from the beginning of the symptoms. The remainder of Professor Fränkel's cases were 18 in number and were convalescent. With 16 of them, whose first symptoms dated back to a period varying from three to seven weeks, positive indications were obtained. Two patients, a boy whose fever had lasted eight days only and a girl whose symptoms were also of short duration, yielded negative results. One boy, who was received into the infirmary on Dec. 13th as being possibly a case of enteric fever, although the clinical symptoms were very doubtful, gave a negative result on Dec. 21st. Professor Fränkel also examined the serum of two men who had probably suffered from enteric fever a year before the outbreak of the present epidemic, but as they had not been under medical care the diagnosis was not certain. Both showed a marked reaction. Professor Fränkel says that if that be the rule, and if every person who has once suffered from enteric fever, even a long time before, continues to show the reaction, this fact may become the cause of errors. Patients suffering from other affections of the intestines, such as typhlitis, tuberculous ulcers, peritonitis, &c., were also examined, but the result was in every instance entirely negative. Professor Fränkel concludes that from a theoretical as well as from a practical point of view Widal's reaction is of the highest importance.

Precautionary Measures against the Plague.

A conference of hygienists will meet at the Imperial Health Office to discuss the measures to be taken in the event of the plague approaching or being introduced into this country, and in accordance with the instructions of the Imperial Chancellor the conference will be attended, not only by the ordinary official staff of the Health Office, but by the members of the extraordinary staff who reside out of Berlin. Vessels coming from Bombay and other ports in India and Persia are to be carefully examined and closely watched, and ships' medical officers will have to give particulars of any deaths that may have occurred during the voyage. The accommodation for travellers at the quarantine stations of Hamburg and Bremen is being increased. The *Vossische Zeitung* discusses Professor Haffkine's proposal to isolate Bombay by a military cordon, and comes to the conclusion that it offers little prospect of success. In 1879, when the plague had broken out in the Russian province of Astrachan, a Commission, composed of the celebrated epidemiologist, the late Professor Hirsch, Staff-Surgeon Dr. Sommerbrod, and Professor Küssner, was sent there to inquire into the practicability of isolating the infected district by means of soldiers, but the Commission, as well as Professor Virchow and Dr. Wernich, opposed any measure of this kind. Good results may possibly be obtained as long as the area of the

Hosted by Google

epidemic is small, but never when the disease has attacked an entire province. For instance, in 1815 the Italian village of Noja was isolated by troops, the place being surrounded by a double deep ditch in which sentries were stationed, a third cordon being posted at a greater distance. The soldiers were strictly forbidden to hold any intercourse with the inhabitants and offenders were punished according to military laws. A soldier who had received playing-cards from the village was sentenced to death, and a villager who was delirious through an attack of the plague approached the cordon and was shot down by the sentries. It is obvious that measures of such severity will be impracticable in modern times. Great alarm was caused the other day in Hamburg by the announcement that a death from plague had occurred on board the British vessel *W. F. Pirrie*, which had arrived in the port from Bombay. It was also said that seven of the crew were still suffering from the disease, but both statements proved to be false, the death in question being caused by pulmonary tuberculosis, and the illness of the other men being due to the consumption of putrid meat. The vessel was, therefore, allowed to enter the port.

Professor Koch's Visit to London.

Dr. Thorne Thorne and Dr. Copeman, of the English Local Government Board, have recently been in Berlin to inquire into the vaccination arrangements of this town. They visited the vaccine institute connected with the central cattle market, where the practical working of the system, by which a sufficient stock of animal lymph is provided, was shown to them. According to the *Berliner Tageblatt* Dr. Thorne Thorne was asked whether it was true that the medical profession in London had deliberately and on purpose taken no notice of Professor Koch during his recent stay in the British metropolis. Dr. Thorne Thorne declared that the imputation of discourtesy was absolutely false, the facts being that on his journey to the Cape Professor Koch spent only one day in London and the name of the hotel where he intended to stay was not previously made known. It was owing to this combination of circumstances, and not through any fault of their own, that the London medical men had no opportunity of welcoming Professor Koch. His scientific eminence is acknowledged everywhere in England and the practical value of his discoveries is fully recognised. It was only natural that English newspapers should express regret that some British bacteriologist had not been selected for the mission to Cape Colony, but these sentiments were in no way inconsistent with a feeling of admiration for Professor Koch's eminent services to medical science. It was understood that he was averse to being the central figure of a public demonstration, but if he would stay longer in London on his return he would certainly meet with a cordial reception.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Plague.

ITALIANS, like the Southern races generally, are prone to panic in anticipation of advancing epidemics—a characteristic aggravated by their long experience of the paralysis of hygienic measures in presence of the invader and also by their well-founded misgivings as to their possessing the immunity which only a sound sanitary tradition—like that of Great Britain, for example—can create. Hence their superstitious reliance on quarantine and sanitary cordons—a reliance which their ablest physicians (Tommasi-Crudeli, among others) have shown to be quite illusory—nay, actively pernicious, as tending to induce a false security and to encourage that neglect of sanitation, public and personal, which forms the best safeguard against all imported disease. We have but to go back to the cholera visitations of 1884 and 1894 to appreciate the alarm at present prevailing in Sicily and Naples in view of a possible invasion of the pestis bubonica. Now, as then, there is no belief in remedial measures when the malady has effected a landing; now, as then, there is a well-grounded consciousness that public hygiene and private habits are such as to invite the enemy and hospitably to entertain him once he is within the gates. Dr. Baccelli, president of the Consiglio Superiore di Sanità, and a clinical teacher, as well as consultant, of great sagacity and experience, has just expressed his views on the situation and claims credit for the Italian Government in having initiated the International Conference which will sit at Venice to consider what action the European Powers should approve for their common protection. Great Britain, he hopes, will see her way to coöperating with the other Powers at the proposed conference; but if she should decline to take part in it he quite appreciates her grounds for so doing. Arguing from his previous practice in cholera epidemics he says her sanitary service afloat, whether in its resources or in its *personnel*, quite justifies her sense of security on such occasions; let alone the fact that the duration of the voyage from Babel Mandeb to her own seaports is long enough to constitute a quarantine superior to what any other State could demand for its own protection.

Jan. 24th.

RUSSIA.

(FROM OUR OWN CORRESPONDENT.)

Russian Precautions against the Plague.

THE spread of the plague in India is being regarded with much interest, and perhaps with some apprehension, in Russia. From a document just published by the Medical Department it seems that the authorities responsible for the sanitary safety of the empire have been making arrangements for some time past to meet the threatened risk. Their first intimation of the existence of plague or a disease suspiciously like it was received in the end of September. On Oct. 10th (22nd) a telegram was received from the Indian Office in London confirming the outbreak and declaring the disease to be bubonic plague; but, so far as could then be judged, of a mild character. On Oct. 23rd (Nov. 4th) the Russian Ministry of the Interior declared Bombay as an "infected" town, this official declaration carrying with it, as a corollary, the necessity for all ships coming from Bombay to Russian ports to carry out certain measures of precaution fixed by the law of 1893. When, in 1894, the plague broke out in Hong-Kong, and the possibility of it spreading to Russia, not only by sea, but also by land, was discussed, it was decided that in the event of plague threatening to invade Russia by means of Persia o Afghanistan certain measures would have to be carried out on the Russian frontiers of those countries. About the 15th (27th) of last December news was received that the plague had appeared in Kurrachee, and as soon as this was confirmed conferences were held between representatives of the three Russian Ministries of War, Finance, and Internal Affairs. Meetings were held on Dec. 16th, 21st, and 28th (Old Style), at which the course followed by previous epidemics of plague was discussed and a plan of action drawn up. The following are the chief points in the plan of campaign:—1. Means must be taken to obtain accurate news of the first appearance of plague in certain specified ports and towns in Persia; for this purpose it is proposed to send Russian medical men to those places where there are not already (as in Teheran and Meshed) Russian consulates or missions. 2. The Persian shores of the Caspian Sea are to be specially watched. 3. "Observation-points" are to be established along the frontiers, dividing respectively Transcaspia and the Caucasus from Persia, Bokhara from Afghanistan, and Turkestan and Semirótchinsk from Kashgar. On the first receipt of news that plague has appeared either in Persia, Afghanistan, or Kashgar the whole series of frontiers will be closed to all passengers and goods, with the exception of certain points, where "inspection stations" will be established. 4. At Batoum, Poti, and Novorossiisk special sanitary control is to be kept over the Turkish feluccas visiting these parts. While the Government authorities are thus taking time by the forelock and wisely disposing their forces to prevent the infection from passing the frontiers, the daily press publishes the most highly-coloured and sensational statements regarding the extent of the plague. The charges against the English Government of inhumanity and indifference, and the complacent comparison of the methods followed by Russia when the small epidemic of plague broke out in the Volga in 1877 with those now practised in India, require no comment. When, however, the leading journals published the total returns of the epidemic from its beginning up to a certain date as the returns for one day only some protest is necessary. Such tactics, whether they have a political object or not, can only do harm by creating in the public mind a state of needless and unfounded alarm.

Hosted by Google

Famine and its Attendant Diseases.

By a noteworthy coincidence Russia is not only the last European country in which an epidemic of plague has occurred, but she is also the last European country that has experienced a widespread famine. In 1890 and 1891, but more particularly in the latter year, the crops failed partly or wholly over very considerable districts of European Russia. Notwithstanding the energetic measures taken by the Government and the outside aid and generous gifts from other countries the suffering was great, and the deaths from inanition and accompanying disease were very numerous. Looking back to the records of the years 1891–92 (for the effects of the famine were still felt in the third year) it is of interest to note what diseases appeared to be rendered more prevalent by the famine. Nearly all diseases were more active and fatal in those years of want, but some showed a special virulence. All forms of "typh" were particularly prevalent. "Spotted typh," as typhus fever is called in Russia, "abdominal typh" or typhoid fever, and undetermined forms of "typh," were all high above the average. Curiously enough, "recurrent typh," or relapsing fever, showed no increase, but rather a diminution on the average of previous years for the whole country. There were, however, in certain parts of the country epidemics of relapsing fever in 1891, and notably in St. Petersburg, where 1005 cases were treated. Nearly a quarter of these were cases occurring in vagrants from the country. A low and virulent form of typhus fever was the most frequent zymotic met with in the famine districts. The number of cases of scurvy was enormously increased, apparently as a direct result of the famine. It was frequently associated with typhus fever, a combination which, according to Pirogof (who was chief surgeon to the Russian troops in the Crimean campaign), was very common both among the defenders and the besiegers during the siege of Sebastopol. As was to be anticipated, diseases of the alimentary tract prevailed to a most unusual extent during the famine years. The death-rate among children from these causes was particularly high. Among adults all forms of gastro-intestinal diseases were met with, from simple catarrh to the most severe and fatal forms of dysentery. These diseases were, of course, largely due to the unusual substances which the starving peasants ate to stay the pangs of hunger. Various forms of nuts, the leaves and bark of trees, and many varieties of inedible herbs and grasses were all pressed into the service and eaten either alone or mixed with the small quantity of available grain to make a larger loaf or a bigger mess of porridge. Even earth and straw are said to have been eaten in many instances. Among the other diseases or symptoms which were observed as accompaniments of starvation was hemeralopia or night-blindness.

Jan. 12th (24th).

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—The following candidates passed in January in the under-mentioned subjects:—

Surgery.—G. P. Ambrose, Westminster Hospital; C. C. Brymer, Montreal; C. H. Church, McGill University; J. McD. McCarthy, Cambridge; G. L. Meredith and A. E. Seller, London Hospital; and J. H. Wilson, Middlesex Hospital.

Medicine, Forensic Medicine, and Midwifery.—A. P. Ambrose, Westminster Hospital; E. S. Langworthy, St. George's Hospital; J. McD. McCarthy, Cambridge; H. R. Marsh, Guy's Hospital; J. H. H. Smyth, St. Mary's Hospital; and H. de P. B. Veale, Leeds.

Medicine and Forensic Medicine.—G. F. May, McGill University.

Forensic Medicine and Midwifery.—J. Gott, King's College; and W. F. Reckitt, Guy's Hospital.

Forensic Medicine.—A. W. H. Edgelow, Charing-cross Hospital; A. P. Square, Middlesex Hospital; and G. S. Thompson, St. George's Hospital.

Midwifery.—P. M. Brittain, St. Bartholomew's Hospital; and E. R. R. Cheesman, Charing-cross Hospital.

The diploma of the society was granted to the following candidates, entitling them to practise Medicine, Surgery, and Midwifery: Messrs. Brymer, Gott, Langworthy, McCarthy, Marsh, Smyth, and Thompson.

INSTITUTE OF CHEMISTRY OF GREAT BRITAIN AND IRELAND.—At the Final Examination for the Associateship (new regulations) in January the following were successful in the subjects indicated:—

Branch A (Mineral Analysis).—Frank Collingridge, B.Sc. Lond., University College, London (passed Intermediate July, 1896); William Ranson Cooper, M.A., B.Sc. R.U.I., Royal University of Ireland and King's College, London; and John Allsopp Walker, B.A. Oxon., Oxford University.

Branch E (Analysis of Water, Food, and Drugs).—Raymond St. George Ross, Owens College, Manchester, and Dresden Polytechnic.

A NEW operating room has been erected at the Beckett Hospital and Dispensary at Barnsley at the sole cost of Mr. Charles Harvey. It contains all the latest improvements and is a most opportune benefaction.

MR. RICHARD DEANE SWEETING, M.A. Oxford, M.B. Trin. Coll. Dublin, D.P.H. Camb., &c., one of the Medical Inspectors of the Local Government Board, has been called to the Bar at Gray's Inn.

THE SANITARY INSTITUTE.—A sessional meeting of the Sanitary Institute will be held at the Parkes Museum on Wednesday, Feb. 10th, when a discussion will be opened by Dr. F. J. Waldo on Sanitary Supervision of Shelters for the Homeless. The chair will be taken at 8 P.M. by Dr. Robert Farquharson, M.P.

SUDDEN DEATH OF A MEDICAL MAN.—On Sunday evening, Jan. 17th, Mr. W. W. Boulton, of Beverley, died suddenly at his residence, Highgate House. He had been in delicate health for several years and had nearly relinquished practice. He was getting out of bed when he fell back and died almost immediately. He has been for many years a magistrate for the borough and was sixty-four years of age.

FOOTBALL CASUALTIES.—In a match between the "Moonlighters" and "Morfa Rangers" at Stradey Park, on the 16th inst. a member of the former team was injured and admitted to the hospital suffering from concussion of the brain.—During a match between Sheffield United and Wolverhampton Wanderers at Bramall-lane, Sheffield, on the 23rd inst, a Wolverhampton player fractured his leg.—In consequence of the severe weather a great many games and matches were on Saturday either abandoned or postponed.

PRESENTATIONS TO MEDICAL MEN.—The members of the St. John Ambulance Class at Shaldon, Devonshire, have recently presented Mr. W. Ker Bell, M.R.C.S. Eng., L.R.C.P. Lond., with a silver-mounted malacca cane as a mark of appreciation of his services as honorary lecturer.—At the Merthyr Tydfil Police-court, on Jan. 21st, the stipendiary magistrate (Mr. North), on behalf of the members of the police who had attended the St. John Ambulance Class, presented Mr. Cornelius Biddle, M.R.C.S. Eng., L.R.C.P. Lond., with a handsome drawing-room clock as a token of appreciation of his services as honorary instructor of the class.

BRIGHTON AND HOVE DISPENSARY.—The annual meeting of the Brighton and Hove Dispensary was held on the premises on Jan. 21st, Alderman Brigden presiding. The report showed that during the past year there had been 15,978 patients, this number being less by 700 than during the year before last. Mr. Thomas Martin had given two donations of £100 each, £100 were given by Mr. E. White, £154 were received from the Hospital Sunday Fund, and £115 from the Hospital Saturday Fund. Special attention was called to the hospital wards in the western branch, which were opened with four beds in the year 1889, but the number of inmates, which had increased from 33 in 1890 to 113 in 1895 and 125 in 1896, had necessitated the number of beds being raised to fifteen. Mr. J. W. Howlett, the former chairman of the Hove Commissioners, had given £750 for the endowment of a cot in the children's ward in memory of his daughter.

WORKHOUSE OVERCROWDING AT STOCKPORT.—At a recent meeting of the Stockport guardians the Workhouse Committee reported that the medical officer was instructed to confer with the master of the workhouse with a view to remedying the overcrowding on the female side of the hospital. The imbecile wards are also said to be overcrowded, and the clerk has written to each member of the Cheshire county council representing a division of the union and also to the local members of the Parkside Asylum Committee, Macclesfield, "pointing out the serious nature of the situation and asking them to do all in their power to bring about the provision of further asylum accommodation for the easterly end of the county with the least possible delay." The Local Government Board has approved of plans for a new workhouse proposed to be erected at Stepping Hill, near Hazel Grove, the cost of which will exceed £100,000. At the same meeting Mr. J. A. Watts was appointed medical officer and public vaccinator for the Hyde district, and Mr. F. Cant was appointed to the same offices for the Bredbury district.

Hosted by Google

A SCHOOL FOR DAUGHTERS OF MEDICAL MEN.—Medical men requiring a school for their daughters may not be generally aware that there is a special establishment for the daughters of medical men, conducted by Mrs. Bennett, the widow of a medical man, and supported by some of the leading members of the profession in London. The address is Pelican House, Champion-hill, Denmark-hill, S.E. The secretary is Major Pead, 14, Victoria-road, Upper Norwood, S.E., who will send prospectus and give all information.

FINES UNDER THE DENTISTS ACT.—The Brighton stipendiary heard on Wednesday the last four cases of a batch of prosecutions for infringement of the Dentists Act, 1878, no fewer than seven gentlemen practising in the town—it was alleged in an illegitimate manner—being summoned by the registered practitioners of dentistry in the town. In two cases heavy penalties were inflicted. E. P. Day, of 15, Old Steine, who gave on his door-plate the name "Dr. Day, Philadelphia, U.S.A.," and A. Ferguson, or Cutler, of 12, East-street, were fined £10 and £3 13*s.* 6*d.* costs each, or twenty-one days' imprisonment. In each case it was alleged by the private inquiry agents employed by the prosecution that, in answer to a question if he was a qualified dentist, the reply was "Yes." Day, it was said, had taken a degree at Philadelphia and had practised since 1879. Ferguson was stated by a registered dentist practising in Brighton to have been his pupil for three years. He knew him as "Cutler," and never as "Ferguson of New York." Two other cases—E. Woods Oxborrow, of the Anglo-American Dental Company, 114, Queen's-road, and H J. Barker, 18, Trafalgar-street—were fined £2 each and £1 1*s.* costs, or fourteen days' imprisonment. In each case the offence was practically admitted. Two other cases fell through. One defendant was actually registered, but carried on a branch. In another case the stipendiary thought the evidence of holding out a qualification insufficient. The remaining case was adjourned pending a decision in the High Court, defendent being one of a number of dentists practising before the passing of the Act who were claiming to have their names placed on the register.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Ministry of Public Health.

A NOTICE of motion to this effect appears in the Order Book of the House of Commons against the name of Mr. Fortescue Flannery—namely: "That in the opinion of this House it is desirable that a Department of Public Health be constituted, and that the same be under the charge of a responsible Minister having a seat in Parliament." No date is named for the discussion of the motion.

Bills Introduced by Private Members.

As usual at the beginning of a session a great number of Bills have been introduced by private Members, but few of them on the present occasion have any special interest for medical men. Sir Walter Foster is responsible for a Bill to provide pensions for poor persons over the age of sixty-five years; Mr. Knowles has introduced again the measure for establishing upon a national basis the registration of plumbers; Sir John Lubbock has also made another attempt for his Shops (Early Closing) Bill; Mr. Cameron has introduced a Bill to amend the Burial Laws, while Mr. Thornton stands sponsor for a measure requiring all vehicles on highways to carry lights after dark. Whether these or other private Members' Bills come to anything depends very much on the amount of time claimed by the Government for their own legislative programme. Mr. Pym has introduced a Bill "to amend the Poor-law Officers' Superannuation Act, 1896, as respects female nurses appointed after commencement of the said Act."

The Adulteration of Food Products.

This question was raised by Mr. Kearley during the Debate on the Address, and the information was conveyed to the House by representatives of the Government that a draft Bill dealing with it has been prepared at the Local Government Board. Mr. Kearley was not able, however, to draw from the Government a pledge that the Bill will be introduced during the present session.

Rabies.

The Departmental Committee on the stamping out of rabies has presented its report, and in this it recommends that the power to issue muzzling orders should be taken from the local authorities who exercise it at present, and revert to the Board of Agriculture, who formerly exercised it. The Committee also makes suggestions as to dogs wearing a collar with the name and address of the owner and as to the importation of unhealthy dogs from abroad.

HOUSE OF COMMONS.

THURSDAY, JAN. 21ST.

The Plague at Bombay.

Lord George Hamilton, Secretary of State for India, said, in reply to a question by Mr. Caldwell, that the attention of the Government of India has been called to the necessity of providing suitable accommodation at Bombay for the isolation and treatment of cases of plague, but he did not propose to interfere with their discretion in regard to moving the troops from Colaba or using the barracks there as plague hospitals. He understood that temporary hospital accommodation of a suitable kind could easily be erected on the open ground in and around Bombay.

The Vaccination Question.

Mr. Logan asked the President of the Local Government Board if it was the intention of the Government to take any steps toward carrying out the recommendations of the Royal Commission on Vaccination during the present session, and whether they would advise boards of guardians to discontinue prosecutions for non-compliance with the Vaccination Acts until the Government were ready to deal with the subject.

Mr. T. W. Russell, in the absence of Mr. Chaplain, replied that the report of the Royal Commission was receiving the consideration of the Local Government Board. As to the second part of the question, it was the duty of boards of guardians to enforce the existing law, and the report of the Royal Commission did not in any way relieve them of their duty in this respect.

Mr. Logan asked the hon. Member if he was aware that many boards of guardians, in spite of the interim report of the Royal Commission, still prosecute people more than once, and whether he did not think it advisable to alter the law in conformity with the recommendations of the Commission.

Mr. Lough said the hon. Member might also tell the House what exactly is the state of the existing law.

No answer was given by Mr. Russell to these questions.

FRIDAY, JAN. 22ND.

Cholera on the "Nubia."

In reply to a question on this subject by Sir Walter Foster, Mr. T. W. Russell said that the *Nubia*, which arrived at Plymouth on Jan. 9th, was reported to have cholera on board. One of the Board's inspectors was immediately instructed to go to Plymouth and to place himself in relation with the port sanitary authority and the port medical officer of health. In all some thirteen cases and four deaths occurred. The action taken was that laid down in the Order of the Board as to cholera, and owing to the excellent arrangements prepared long in advance by the Plymouth port authority isolation of the sick was at once carried out, the healthy passengers were allowed on giving their addresses to proceed to their respective homes, and the ship after the requisite measures of disinfection was allowed to continue her voyage to the Port of London. The troops were transferred to shore under the direction of the military authorities. No extension of the disease occurred to any persons beyond those attacked on board, and the results fully justified the action which was taken in this country of dealing with diseases of foreign importation by means of isolation and without resort to any such measures of quarantine as were involved in the detention of healthy persons either in hospital or in an infected vessel.

Flogging a Prisoner.

Mr. J. A. Pease addressed a long question to the Home Secretary with reference to the flogging of a prisoner named Almond in Carlisle Prison.—Sir Mattthew White Ridley, in the course of his reply, explained that Almond made his escape from the prison by cutting through the bar of his cell window with a file. On his re-capture his case was referred to the Visiting Committee to be dealt with under the powers conferred upon them by the Prison Acts, and they, in the exercise of their discretion, and having regard especially to the fact that in addition to his escape he was also charged with repeated offences against prison discipline, and his character was bad, decided to order him eighteen lashes. The allegations as to his screams being heard all over the prison were unfounded; he uttered no sound and suffered no ill effects, but was able to dress himself and go about his work. The skin was not broken. The punishment was legal, and he had no power to interfere with the discretion of the justices which was vested in them by law, though as a rule a mere attempt at escape, if unaccompanied by aggravating circumstances, would not be punished by flogging.

Bubonic Plague in Bombay.

Lord George Hamilton made the following statement on this subject—viz.: The plague was identified at Bombay in September last. On Oct. 2nd wide powers were conferred on the chief executive officer of the city, who is a Government official, to take whatever measures were found necessary to prevent the epidemic from spreading. Large sums of money were voted for the purpose by the corporation. The Government appointed a special medical committee to investigate and advise; scientific experts came from other parts of India to report upon the disease and its prevention; while additional medical men and a large staff of workers were employed to carry out at once the special sanitary measures in Bombay advocated by the committee of experts. The epidemic appeared to be abating in November, but from Dec. 1st it grew more severe. The plague spread to Karachi in December and is now suspected to be epidemic in Poona. Over 2500 plague deaths have occurred in Bombay, over 300 in Karachi, and about 100 sporadic cases elsewhere. As the House is aware from newspaper telegrams, the plague has caused much terror among the people of Bombay and in the adjacent country, but the disease had not so far appeared in epidemic form at any place besides Poona outside the cities of Bombay and Karachi. The sporadic cases of which I spoke, excepting at Poona, occurred almost entirely among fugitives from the two plague-stricken cities. The efforts of the Government and of the corporation, between whom hearty coöperation exists, were devoted to relieving sufferers from the plague, to checking its extension in Bombay and Karachi, and to preventing its spread elsewhere. Hospital space was increased, special plague hospitals were provided for six different sections of the community, and are being prepared for two other sections. House-to-house visitation of infected quarters is being carried out under medical supervision. Every suspected case of plague that is not at once removed to the hospital is isolated as far as practicable. Every house where a plague case has occurred is disinfected and is, as far as possible, vacated, temporary accommodation being provided elsewhere. Insanitary houses are pulled down, in others partitions

Hosted by Google

are removed or ventilation introduced. Special sanitary precautions and improvements have been carried out in the backward parts of Bombay city. A fuller staff of medical men and Indian medical men is being organised, and the Bombay Government will rely on England for a temporary staff of medical men and nurses if more aid is required. To prevent the spread of plague to other parts of India passengers leaving Bombay, Karachi or Poona by rail, road, or sea are inspected by medical officers, and persons travelling or alighting at the larger stations are stopped and removed for treatment if they are suspected of being plague-stricken. In case pilgrims to the Moslem holy places might carry plague into the Red Sea the Government of India have—empowered by law—declared that from Feb. 1st Bombay and Karachi shall cease for the present to be ports of departure for pilgrims. The Bombay Government report that the corporations are granting all necessary funds, while the executive and medical officers there and elsewhere are doing all that can be done though prompt suppression of the epidemic has not been attained. The Government of India report their belief that the arrangements at railway stations for checking the spread of disease are working well; but they are inquiring whether further measures are needed, which, if necessary, will be given. I believe that these remedial and precautionary measures are daily becoming more stringent and more effective; neither self-sacrificing work nor money is being stinted. If it has been difficult to secure the coöperation of some sections of the Indian population to promote the sanitary and preventive measures for the arrest and stamping-out of this pestilence, yet in other quarters loyal assistance and effective self-help have been displayed. I am hopeful that the continuous energy and vigilance shown by the Government and the local authorities and the rigorous measures they have adopted are beginning to make real impression upon that epidemic, and that we may for the future note its decline. I should add that the experts some time back expressed the view that during the winter months some increase in the epidemic might be expected. As I came into the House I received a telegram from the Governor of Bombay to the effect that he learns that alarmist and greatly exaggerated telegrams in reference to plague are being sent from Bombay, and he hopes that great caution will be shown before accepting the information as true. Only four pure Europeans have died from the plague, including a medical man and a nurse. Amongst the dock labourers and Port Trust servants the deaths and sickness are very small indeed.

MONDAY, JAN. 25TH.

Dangerous Trades.

Sir Matthew White Ridley, Secretary of State for Home Affairs, said, in reply to a question, that out of the seven processes named in the report of the Committee on Dangerous Trades he had already seen his way to certifying two as dangerous under the Act of 1891. Special rules embodying most of the recommendations of the Committee had been issued for one of these—the bottling of aerated waters—and would shortly be issued for the other—the vulcanising of indiarubber by means of bisulphide of carbon. With regard to the remaining five, a similar course would probably be necessary in the case of some, if not all; but there were legal and administrative considerations which made it difficult to give full and adequate effect in the form of special rules to the suggestions of the Committee. For the present, therefore, he must reserve his decision on this point, but in the meantime steps were being taken by the factory inspectors to watch these processes and to secure the improvement of the conditions under which work was carried on.

Venereal Disease among the Troops in India.

Lord George Hamilton made the following statement on this subject in reply to a series of questions—viz.: It is the case that the total aggregate admissions to hospital for venereal disease among the British troops in India amounted in the year 1895 to 522 per 1000, but this does not mean that 522 men per 1000 were separately and individually admitted, still less does it indicate that 522 soldiers per 1000 are incapacitated for duty from this cause. It is calculated on the latest returns that an average permanent deduction of 46 per 1000 is the loss entailed by these diseases. The facts as to the serious increase of this disease in India are now being inquired into by a departmental committee, on receipt of whose report Her Majesty's Government will carefully consider the whole subject.

Public Health Bill for Scotland.

The Bill of the Government to consolidate and amend the laws relating to public health in Scotland was introduced at this sitting without any explanatory statement and formally read a first time.

TUESDAY, JAN. 26TH.

Malta and the Indian Plague.

Mr. Chamberlain, replying to a question put by Sir Walter Foster, said it is the case that the Governor of Malta, after first imposing a twenty days' quarantine, has since issued a total prohibition on all vessels, however healthy they may be, arriving from India. His predecessors and he had continually urged the Government of Malta to adopt the more scientific and convenient methods of preventing the introduction and spread of foreign diseases instead of the stringent system of quarantine hitherto in use, but partly from the supposed necessity of conforming to the practice of Italy, and partly from the inveterate belief of the population of Malta in the necessity of the strictest quarantine which might lead to disturbance if the rules were relaxed, they had not as yet succeeded in effecting the change. He was now in correspondence with the Governor and had pointed out to the Colonial Government the serious injury which was being inflicted, not only on commerce, but on the interest of Malta by the action of the Government, and he should be glad if his remonstrances might induce them to adopt a more reasonable course.

Poor-law Officers in Ireland.

Mr. Clancy introduced at this sitting a Bill to provide for the Superannuation of Poor-law Officers in Ireland.

BOOKS, ETC., RECEIVED.

BERGMANN, J. F., Wiesbaden.
Jahresbericht über die Fortschritte auf dem Gebiete der Chirurgie. Von Prof. Dr. Hildebrand. I. Jahrgang: Bericht über das Jahr 1895. 1896.

Northern Central (Gynæcological, 2.30 P.M.)

FRIDAY (5th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.).

SATURDAY (6th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (1st).—ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (40, Leicester-square, W.C.).—8 P.M. Communications:—Mr. H. W. Messenger: A Case of Double Harelip, with Cleft of the Hard and Soft Palates.—Mr. G. H. Bowden: A Case of Deafness following Bilateral Dislocation after Extraction of Molar Teeth.—Mr. H. Baldwin: Cement and Amalgam Fillings. Paper:—Mr. J. H. Badcock: Copper Amalgam, its Merits and Demerits.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. F. de Havilland Hall: Disease of the Nose and Throat in Relation to General Medicine. (Lettsomian Lecture.)

TUESDAY (2nd).—PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Papers: Mr. J. W. W. Stephens and Mr. C. D. Parfitt: Three Cases of Hæmorrhagic Diphtheria.—Dr. A. E. Garrod: Pneumococcous Endocarditis of a Two-cuspid Aortic Valve with Malformation of the Liver.—Dr. H. Mackenzie and Mr. W. Edmunds: Persistence of Thymus in Graves' Disease. Card Specimens:—Mr. D. Drew: Obturator Hernia.—Dr. Hebb: Tumour of Spinal Cord.

WEDNESDAY (3rd).—OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Mr. Doran, Dr. J. Phillips and others. Paper;—Dr. A. E. Giles: The Cyclical or Wave Theory of Menstruation, with Observations on the Variations in Pulse and Temperature in relation to Menstruation. Annual Meeting. The President (Dr. Champneys) will deliver the Annual Address.

THURSDAY (4th).—SOCIETY OF ARTS.—8 P.M. Prof. J. A. Ewing: The Mechanical Production of Cold. (Howard Lecture.)

HARVEIAN SOCIETY (Stafford Rooms, Titchborne-street, Edgware-road, W.).—8.30 P.M. Clinical Evening.

FRIDAY (5th).—WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenwich-road, S.E.).—8.15 P.M. Mr. G. Herschell: On Chronic Fæcal Retention, its Consequences and Treatment.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—8 P.M. Discussion on the Menopause. Opened by Dr. A. Routh, Dr. W. Hunter, and Dr. C. Tuke.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

TUESDAY (2nd).—CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL.—4 P.M. Dr. D. Grant: The Diagnosis and Treatment of Obstructive Deafness, apart from Pain or Discharge.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Dr. Tooth: Lecture.

WEDNESDAY (3rd).—WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.)—5 P.M. Dr. D. Hood: Appendicitis from a Medical Point of View.

HOSPITAL FOR CONSUMPTION, &c., (Brompton).—4 P.M. Dr. Schorstein: Diagnosis of Early Tuberculosis.

FRIDAY (5th).—CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL.—4 P.M. Mr. W. Wingrave: The Clinical and Pathological Aspects of Atrophic Rhinitis.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Dr. Beevor: Cerebral Localisation.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index for the second volume of 1896 was given in the issue of Dec. 26th last. The practice of supplying loose copies has been discontinued, the Index having been placed in the centre of the journal, whence it can easily be detached, and placed either at the beginning or at the end of the volume.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1896 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.* (Local bookbinders will charge about 1*s.* for binding the numbers in these cases.)

To be obtained on application to the Manager, accompanied by remittance.

A MYSTERIOUS LETTER.

THERE was once a lady who incurred a bill. She left the neighbourhood, and her creditor, a medical man, gave instructions that her account should be sent in. The lady paid notwithstanding that she considered it "an overcharge for a bilious attack," seeing that her husband "lost considerably by the failure of the —— Bank," and her letter includes the following remarkable sentence: "I am beginning to see how it is the hospitals are getting so many female nurses They do the M.D.'s work much cheeper (*sic*) and just as well so it will eventually come to this, they will get a cradle and put the M.D.'s in and rock them to sleep and take the whole duty upon themselves, and then we will have woman's rights and clear consciences." That the good lady meant to be offensive is clear, but nothing else in her meaning is equally lucid. In what way efficient nursing at a hospital "cheepens" M.D.'s work no one can guess. How the rocking the M.D.'s in cradles would be an assertion of woman's rights is a second conundrum. We thought that the staunch upholder of women's rights would have nothing to do with cradles. And, again, how the rocking of M.D.'s in cradles will clear the consciences of ladies who do not pay their medical men beggars, conjecture.

THE TREATMENT OF CARBUNCLE.

To the Editors of THE LANCET.

SIRS,—The germicidal treatment of carbuncle is not of recent date, but I venture to think also not of general adoption. The advantage, however, of simply dressing the carbuncle after free and early incision by iodoform and Listerian dressings has been so considerable in my hands that I beg leave to refer to it in THE LANCET. My last case of carbuncle (for instance), of about the size of a five-shilling piece, was treated by the usual cruciform incision and dressed as above indicated on the Friday of one week. The whole of the slough had "shelled out" by the Tuesday of the following week. There was none of the tedious and painful disintegration involved in the old process of poulticing and the healthy granulating action of the tissues literally pushed forwards the slough, chiefly in one mass, which was withdrawn by the forceps. By the end of the same week the edges of the wound, brought into close contact by adhesive plaster, had nearly united, so as to leave ultimately a most insignificant scar. This last event, too, is of course frequently a most desirable event. My patient was able to attend to his business during the time with trifling inconvenience. The situation of the carbuncle was at the back of the neck.

I am, Sirs, yours faithfully,

Jan. 24th, 1897. W. J. V. HARLE.

Service.—The case has not been put before us previously. The presents cannot be regarded legally as payment unless there is evidence that they were given and accepted as such. Again, a medical man is entitled to charge for his services even if the patient be in his own profession, and Dr. A—— is, of course, not in active practice. The whole matter is one for mutual arrangement. If an action is brought by Dr. D—— for reasonable fees he will certainly win it under the circumstances detailed by our correspondent unless it can be shown that without doubt the presents were made in lieu of other payment. Our correspondent will remember that we are expressing an opinion only upon the facts as laid before us.

LIFE ASSURANCE AND PENSION FOR NURSES.

THE Pearl Life Assurance Company have made a small departure that we can understand will prove very welcome to the class which it is designed to benefit. They have prepared a table combining life assurance with annuity in such a way that in the event of the death of the insured occurring before a certain date the sum of £25 is paid by the company, together with the surrender value of the premiums already paid. If the insured survives to the date in question she becomes entitled to a pension. An example will explain exactly what the company offer. Suppose the age of a nurse at her next birthday to be thirty-five years, and suppose she desires to derive a pension when she is fifty-five years, she would have to pay £2 5s. 1*d.* per quarter for twenty years. If she dies before attaining the age of fifty-five years she will be insured by the company in the sum of £25 together with the surrender value of the policy, in which direction the company are prepared to give what we consider highly liberal terms. If she lives until fifty-five years she will be placed in receipt of £5 per quarter for the rest of her life.

Astonished has not quoted to us the rules of the institution placing the treatment of all patients absolutely under himself. Certainly no change in such rules should have been made without giving him due notice. He is, perhaps, aware that to allow patients to be treated within the walls of the cottage hospital by their usual medical attendant is not without precedent, and that committees find the procedure to work well and to lead to more regular public support.

G. E. J.—The advertisement is unfortunate, but let us be fair. There is on the face of it no evidence that the medical man has countenanced the publicity, while all who are acquainted with him know that he is the last man to desire any notoriety obtained in an unworthy manner. The grateful journalist is evidently a stranger to the law of medical etiquette, and has said a good word for his medical man exactly as he would have extolled a convincing sermon from his clergyman, or the able conduct of a case by his lawyers. That the paragraph was written as part payment of the surgeon in lieu of cash fees is an absurd and unworthy assumption.

A CRUISE ON A WHALER.

To the Editors of THE LANCET.

SIRS,—May I trouble you, or any of your readers, on behalf of a young friend anxious to see something of whaling, to let me know through THE LANCET, at which depôt an application for an unqualified man may be made, from what port vessels sail, and any information as to necessaries useful throughout the cruise. Should answers to my queries be not in your keeping, would you kindly indicate where information may be had.—I am, Sirs, yours faithfully,

Jan. 26th, 1897. SCRUTATOR, M.D.

"THE UNQUALIFIED ASSISTANT."

To the Editors of THE LANCET.

SIRS,—Your correspondent "Student" may assure himself with perfect truth that the remarks of the President of the General Medical Council to Mr. Adamson on the subject of unqualified assistants commend themselves to the feeling of the main bulk of the general practitioners in England. It seems to me that if we would deny the right of the abortion-procuring midwife, the prescribing chemist, and the "ambulantic" policeman to hang upon the skirts of the medical profession we must first of all shake off the grasp of our own bastard half-brother—the unqualified assistant. To purify a river the ameliorating measures must be brought to bear upon the main stream and the improvement in the condition of the minor water-courses, creeks, and backwaters will follow as a matter of course; to reverse the process is at once ridiculous and futile. Your correspondent gives way to unnecessary alarm if he thinks that the publication of the person's name in penal cases will militate against that person's chance when he becomes qualified. He may calm his fears. In the case of the average unqualified assistant the probability is of the remotest that he will ever be other than what he is. No matter how vastly superior he deems the knowledge of his "business" learned from his "kindly" principal, who points out his mistakes (and signs the death certificates), to that gleaned from the conflicting theories of our learned "professors," the fact remains that the powers that be will refuse to accept the one for the other when he presents himself, if he ever does, for examination. Again, your correspondent disproves his own argument in attempting to draw a comparison between himself and a law student. It is essential for the latter to be articled for five years to a solicitor; this is analogous with the five years spent at a hospital in the case of the medical student. Should the law student for any reason be unable to put in the five years he would not be allowed to go up for examination, but he would not be allowed to practise as an unqualified solicitor. Finally, in these days of long curriculum and compulsory attendance at general and special hospitals the student who falls astern and becomes an unqualified assistant never regains his position, still less does he make headway. His knowledge of medicine is gained from the bottles in the surgery, their doses, and what they are "good for" from a pocket "aid." He finds himself at, fifty a disappointed Ishmaelite, going about from situation to situation with a growing feeling that his oft-advertised full curriculum, enthusiastic reception at midwifery cases, and Nimrod-like qualities with all manner of horseflesh, are hardly reckoned as a sufficient set-off to an insidiously developed, but firmly established predilection for every variety of strong drink.

I am, Sirs, yours truly,

Jan. 22nd, 1897. RIPARIAN.

Miss L. Waddington.—The letter is not suitable to our columns. It should be sent to some journal devoted to the interests of nursing.

Veritas.—The right course is certainly to lay the position fully before the registrar. The law says that the practitioner in attendance during the last illness should sign to certify. In the rare circumstances where the medical attendant has gone from the neighbourhood, but left behind him complete notes of the case so that the cause of death cannot be in doubt, the registrar should be informed by the successor in the practice or hospital appointment of the state of the matter. The difficulty cannot very often arise, as it cannot be a usual occurrence that between the last visit paid to a patient in his last illness and the occurrence of death the medical man in charge has reached a destination where he cannot readily be communicated with.

MIDWIVES AND THEIR WAYS.

THE following circular is, we are informed by a correspondent, circulated to the public in Grimsby:—

MRS. PHILLIPS,
CERTIFIED MIDWIFE,
(from Queen Charlotte's Hospital, London,)
449, WEELSBY TERRACE, CLEETHORPE ROAD, GRIMSBY.

449, Weelsby-terrace, Cleethorpe-road, Grimsby.

MADAM,—Having been in practice in Grimsby for three years, I take this opportunity of thanking my numerous patients for their kind confidence placed in me during that time.

Since obtaining my diplomas from London I have attended over a thousand midwifery cases, and am thankful to say I have not had one death or inquest.

I trust by prompt and conscientious attention to my duties to obtain a further share of public confidence and support.

Fee, 10*s.* 6*d.* I am, yours faithfully,

449, Cleethorpe-road, Weelsby-terrace, Grimsby. E. PHILLIPS.

This little circular contains also the picture of an earnest-looking female in nursing costume—some little gravity in the expression being doubtless produced by her responsible labours. The address of the midwife it will be noted is printed no less than three times with variation. Medical men in the neighbourhood must find this enterprising female an unpleasant neighbour.

"THE SWALLOWING OF LEAD PELLETS."

To the Editors of THE LANCET.

SIRS,—With reference to the letter in THE LANCET of Jan. 23rd from Mr. Mason of Burton-on-Trent on the practice of swallowing shot, I may say that about twenty-five years ago a brother of mine, now dead, was a curate in that town, and at the time he informed me that in the course of his parochial visitations he had at various times been told (generally by elderly women) that they were in the habit of swallowing shot for the purpose of preventing the lights rising. He was also shown the shot used. As Mr. Mason's letter confirms my brother's statement it appears that this practice has been now followed in that locality for a long period. It would be interesting to know if it is confined to that part of the country, as I have not heard of it elsewhere.

I am, Sirs, yours faithfully,

J. R. WHITE, M.B., T.C. Dub.

Kelvedon Hatch, Brentwood, Jan. 24th, 1897.

Dr. Leonard Molloy.—It is impossible to answer in general terms. We presume our correspondent refers to some particular case. The medical superintendent might easily be compelled to examine a patient in the absence of the medical man under whose care the case was. The date of discharge of a patient might for reasons of convenience have to be left to the superintendent, but the fitness of a patient to be discharged would be settled by the medical man in charge. We presume that the duties of the superintendent have been defined.

ACCRINGTON DISPENSARY AND ITS MEDICAL OFFICER.

THE *Manchester Guardian* of Jan. 22nd contains the following account of an action brought by a dispensary against a late medical officer:—

"Yesterday at the Accrington County Court, before Judge Coventry, Mr. R. K. Whittaker, solicitor, applied for an interim injunction in the name of the trustees of the Accrington and District Medical Dispensary against Dr. John Neild Cooper, late medical officer to the dispensary, to prevent him from practising as a physician and surgeon in Accrington. The case is fixed for hearing at the next Haslingden Court, and application was made to prevent Dr. Cooper practising in the meantime. Mr. Whittaker read affidavits stating that Dr. Cooper was engaged as medical officer to the dispensary in June, 1896, and that he signed an agreement binding himself in case he left the Dispensary not to practise in Accrington for three years, or within a radius of three miles, and that if he did so he should be liable to a fine of £2 per day. The damages claimed were £50. It was alleged that the defendant was practising in Edgar-street, Accrington, and that he was canvassing members of the dispensary and promising them medical attendance on the same terms as members of the dispensary were treated. Dr. Cooper was discharged as medical officer to the dispensary on Dec. 22nd, and the affidavits alleged that by his canvassing and practice he was doing injury to the institution.—Mr. Speake, solicitor for the defendant, opposed the grant of an interim injunction, and denied that his client was canvassing the members of the dispensary. He also alleged that the agreement had been broken and that there was a good defence against the injunction being granted when the case came to be heard.—His Honour: Is your client willing to keep an account of the business he does until the hearing of the case?—Mr. Speake: Perfectly.—Mr. Whittaker: And promise not to canvass?—Mr. Speake: We deny it.—His Honour: I shall make no restraining order until I hear the case. The defendant must keep an account of the business done."

L.S.A.—We cannot say to whom the fee legally belongs, as this would be determined by agreement between principal and assistant. In the absence of mention of the matter in the agreement it would be determined by any legal decision in the matter already given; but we are not aware that the question has ever been decided in a court of law. As a matter of custom these fees belong to the principal, and we believe that a legal decision would endorse this custom. As a matter of mutual good feeling they are often divided between him and his locum-tenent or assistant.

DR. RENTOUL'S EXPENSES FUND.

To the Editors of THE LANCET.

SIRS,—The following is a first list of subscriptions to the fund.

"MADE IN GERMANY."

To the Editors of THE LANCET.

SIRS,—I shall be obliged if you will kindly insert this in your next issue. Some time ago I got a London surgical instrument firm to make me a small capsule for use in aural work. A few months ago an American friend of mine saw me using the capsule and liking it asked me where I had obtained it. I gave him the name of the firm. As he was leaving England altogether in a couple of weeks he was unable to give the order as the firm had not the article in stock. Before going home he went to Berlin for a few days and there saw the same thing in an instrument shop, where it was sold as a native idea. A little later it may appear again in London with a German name attached to it possibly, when, no doubt, it will be looked upon with awe by those who are so fond of German goods.

I am, Sirs, yours faithfully,

Devonshire-street, W., Jan. 22nd, 1897. GRIFFITH C. WILKIN.

PERSISTENT HYALOID ARTERY.

DR. CLARENCE A. VEASEY relates in the *Philadelphia Polyclinic* a case of persistent hyaloid artery extending, as in fœtal life, from the central artery of the retina to the posterior capsule of the lens. The left eye only was affected; it showed eighteen dioptres of myopia and vision amounted only to the counting of fingers at two feet.

Fair Play.—There is nothing illegal or "infamous in a professional respect" in B.'s conduct, so that A. cannot expect the General Medical Council to take cognizance of the matter. In the circumstances described to us B.'s application for the Poor Law appointment was decidedly not graceful, while his call upon A.'s patient with an offer of future services was contrary to all the accepted canons of medical etiquette.

UNFAIR COMPETITION.

WE have received a copy of the *Eastern Daily Gazette* which contains among other "Northern Notes" two paragraphs with reference to the appointment of medical superintendent to the Middlesborough Asylum. The first one says that the asylum is "now approaching completion," and gives the name of a gentleman who has applied for the post of medical superintendent, with an editorial endorsement of his fitness for the position. The second paragraph is a long testimonial from the superintendent of one of the best known asylums in the kingdom where Dr. X—— is at present a resident assistant. We are curious to know how this document could have reached the public press, for it would be manifest to every one that the printing of such strong recommendations of Dr. X—— gives him an unfair advantage over any other competitors who may apply for the post.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Reliable Products of Modern Pharmacy.

THYROID FEEDING IN CASES OF STUNTED GROWTH.

On the subject of thyroid feeding in cases of stunted growth Dr. Johann Julius Schmidt contributes an interesting article to the Vienna THERAPEUTISCHE WOCHENSCHRIFT the conclusions in which are supported by statistics and clinical reports. In the course of this communication Dr. Schmidt says:—

"I will add a few remarks regarding preparations of the Thyroid Gland, their doses, accessory symptoms and duration of feeding. Since reading Dr. Ewald's work on 'Disease of the Thyroid Gland,' in which their efficacy is highly praised, I have exclusively used the 'Tabloids' of Burroughs, Wellcome & Co. As experiments on animals point to the fact that moderate doses best accelerate growth I have only given my patients one 'Tabloid' daily.

"I tried Thyroiodin in two cases for several months. I have come to the conclusion, however, that during this time growth did not progress as rapidly as it did throughout the period that thyroid 'Tabloids' were successfully administered.

"I cannot say whether the daily dose of Thyroiodin was too small, or whether 'Tabloids' of Thyroid Gland contain a second important body as active albuminous principle which influences the growth of bone, a contention supported by several authors.

"In order to achieve a full measure of success, the 'Tabloid' feeding must be continued for a year or even longer period. The energy of growth however, which averages 1 cm. per month, seems to decrease in the second year.

"In those cases in which thyroid feeding has been carried out as above described and under the control of a physician, I have been unable to find either symptoms of the so-called thyroidism (nausea, headache, palpitation of the heart, and increase of pulse rate), or other troubles, such as albuminuria or glycosuria.

"I had only observed during the first three to four weeks of thyroid feeding an increase of diuresis, accompanied by the well known decrease of weight, though in a slight degree. However, later I was able to confirm the general improved state of health of all the patients, and an increase in weight corresponding to the general growth of the body.

"I have come to the conclusion that thyroid feeding influences stunted growth favourably. It has, moreover, been proved that even one and a half years' feeding with small doses is without danger to the patient. It seems, therefore, decidedly our duty to try this form of treatment in cases of stunted growth."

Thyroid Gland "Tabloids" (B., W. & Co.), 1½ gr. and 5 gr. are supplied in bottles of 100; the 1½ gr. "Tabloids at 10d., and the 5 gr. "Tabloids" at 2s. per bottle.

SAXIN "TABLOIDS."

Saxin has been aptly termed "the sweetest thing on earth," being about 600 times sweeter than sugar, and double the sweetness of saccharin. It is perfectly harmless as it undergoes no change in its passage through the digestive system, but simply imparts its delicate sweet flavour to the food or fluid with which it is used. For these reasons it is indicated in such conditions of disease as diabetes mellitus, gout, obesity, glycosuria, &c, in which the patient is debarred from taking sugar and yet retains an intense desire for the sweet flavour to which the palate has, by long use, become accustomed.

Saxin has important qualities which render it superior to other sweetening substances. It is unfermentable and permanent. It operates antiseptically and prevents decomposition. In flavour it is more delicate than any other sweetening agent, and in the shape of "Saxin Tabloids," ¼ gr. each, it provides the maximum amount of sweetening power in the smallest possible space. A small bottle, containing 100 or 200 "Tabloids," can be carried in the vest pocket without the slightest inconvenience, and thus the patient, who must avoid sugar, can have a delicately flavoured, harmless sweetening agent always handy, when at business, or when travelling at home or abroad.

Saxin "Tabloids," ¼ gr., are each equivalent to one lump of best loaf sugar and are supplied in bottles of 100 and 200 "Tabloids" at 7d. and 1s. 1d. per bottle.

CASCARA SAGRADA & BELLADONNA "TABLOIDS" (B., W. & CO.).

A valuable combination containing intestinal stimulant, tonic and laxative ingredients, the formula being:—

Cascara Sagrada Extract	...	...	2 gr.
Nux Vomica Extract	...	...	¼ gr.
Belladonna Extract	...	...	⅓ gr.
Capsicine	...	...	⅛ gr.

The MEDICAL PRESS, Dec. 16th, says: "The 'Tabloids being sugar-coated constitute a very agreeable form of exhibiting the combination."

Compound Cascara Sagrada and Belladonna "Tabloids" are supplied in bottles of 25 and 100 at 9d. and 1s. 6d. per bottle.

EMOL-KELEET.

Since our earlier notices to the medical profession regarding this preparation we have received many encouraging reports of the beneficial effects of its use in Surgery and Dermatology. It has not only been prescribed as an absorbent, anti-pruritic, and emollient, but also as a diluent for such antiseptic agents as Loretin, Dermatol, Iodoform, Boric Acid, Chrysophanic Acid, Hydro-Naphthol, &c. Owing to the fact that it is a natural powder containing a large proportion of native silicates, "Emol Keleet" is chemically stable, and is therefore freely prescribed as a diluent for potent medicinal agents without fear of combination taking place. In addition to these chemical advantages, its soft, silky texture, soothing influence, and other physical qualities enhance its healing action. It has proved successful for drying weeping surfaces when all other drying and dusting powders have failed.

THE LANCET, in an appreciative notice of this preparation, says: "On account of its remarkable velvety smoothness it should possess a unique value as a dusting powder in the treatment of cutaneous diseases, &c., and for allaying irritation. We have not examined a more unctuous earth."

Price to the medical profession, 9d. per box.

The Lettsomian Lectures

ON

DISEASES OF THE NOSE AND THROAT IN RELATION TO GENERAL MEDICINE.

Delivered before the Medical Society of London,

BY F. DE HAVILLAND HALL, M.D., F.R.C.P. LOND.,

PHYSICIAN TO THE WESTMINSTER HOSPITAL, AND JOINT LECTURER ON THE PRINCIPLES AND PRACTICE OF MEDICINE IN THE WESTMINSTER HOSPITAL MEDICAL SCHOOL.

LECTURE I.[1]

Delivered on Feb. 1st, 1897.

MR. PRESIDENT AND GENTLEMEN,—When your Council did me the honour of requesting me to deliver the Lettsomian Lectures my first thought was, Had I anything worthy of presentation before so distinguished an audience? It then occurred to me that between the position of the Medical Society of London and my own there was a certain resemblance. The society is always ready to receive papers on general medicine; at the same time it welcomes with equal pleasure the contributions of those of its Fellows who have devoted themselves to special branches of practice. My position is this: I am physician to a general hospital, and consequently all forms of disease come under my care; at the same time, in virtue of having held for nearly twenty years the post of physician in charge of the Nose and Throat Department at the Westminster Hospital, I may be considered to have more or less special knowledge of the diseases of the nose and throat. This being our respective positions I thought that I could not do better than submit for your acceptance some reflections on the relation existing between diseases of the nose and throat and general medicine, as in the dual capacity in which I stand I am perhaps better able to see the two sides of the question than either the pure specialist or the general practitioner

There are two chief methods of treating the subject I have chosen. You can either briefly run over the principal general diseases and point out the nose and throat complications which occur during their course, or you can start with the various diseases of the nose and throat and then mention the conditions under which they may be met. I have selected the former plan as being the more suitable for my purpose. I therefore propose to pass in review some of the principal general and local diseases of the body and describe the various affections of the nose and throat which occur during their course. If you will pardon a digression I should like to take this opportunity of emphasising the importance of the laryngoscope as a means of diagnosis and treatment. I often hear it compared with the ophthalmoscope, and I have heard students say that they have not time to perfect themselves in both, so they have chosen the ophthalmoscope. For the general practitioner, however, there can be no sort of doubt that the laryngoscope is immensely more useful than the ophthalmoscope. I am ready to admit that the ophthalmoscope is very often useful in settling a diagnosis, but as far as I can learn there are only two conditions in which the ophthalmoscope is essential to a diagnosis—viz., the presence of optic neuritis as indicative of some organic disease within the brain and the occurrence of retinitis as an early sign of renal disease. Its use from a therapeutic point of view is extremely limited. On the other hand, I might well occupy the whole of one of these lectures in describing the use of the laryngoscope in the diagnosis and treatment of disease, and I know of no speciality in which even a moderate amount of knowledge is so sure of a good harvest as that of laryngoscopy. The general practitioner who has made himself familiar with the laryngoscope has largely increased his sphere of usefulness. Far be it from me to run down the ophthalmoscope; on the contrary, I hope that the time will come ere long when no one will be licensed to practise unless he can show that he is capable of using the laryngoscope, ophthalmoscope, and other instrumental means of diagnosis. The use of the nasal speculum and rhinoscope is so closely connected with that of the laryngoscope that the student who learns how to use the latter will, as a matter of course, employ the former. This digression will, I hope, be pardoned, but I felt it a duty to speak plainly on the subject, as, owing to the deficiency in the system of examination as now carried on, students are not induced to perfect themselves in the use of the laryngoscope. Before entering upon a description of the nose and throat affections of the acute specific diseases I would like to accentuate the extreme importance of the nose and throat as the chief portals of entrance of the poisons, whatever they may be, which give rise to these diseases. Evidence is gradually being accumulated which points to the conclusion that people who suffer from nasal affections are more liable to contract infectious diseases, especially diphtheria, than healthy persons. In erysipelas of the face it is very frequently found that there is some chronic nasal affection and that the erysipelatous blush started from the nose. This I have often been able to demonstrate in hospital cases under my care. If we except water-borne diseases, such as cholera and dysentery, almost all the other infectious diseases are conveyed by the air, and hence the morbific agent usually enters by way of the nasal cavities and pharynx, and here it proliferates during the first stage of incubation. Two cases of artificially produced disease of the nose brought forcibly before me the risk of operative procedures on the nasal mucous membrane in persons exposed to infectious diseases. In both these cases I had used the galvano-cautery for the cure of hypertrophic rhinitis, and in both symptoms of scarlet fever manifested themselves two or three days after the application of the cautery. The first case might be merely a coincidence, but the second case was that of a medical man who, as house physician at a London hospital, had been constantly exposed to the infection of scarlet fever without effect until I unluckily made a way, as I believe, for the entrance of the germs through the abraded mucous membrane of the nose. The practical conclusions that I would draw from the above is the advisability of abstaining from operative procedures on the nasal mucous membrane during epidemics of influenza and other infectious diseases, as well as in the case of persons liable to be brought in contact with such diseases. I have also abstained from operating on medical students and others whose duties take them into the dissecting or post-mortem rooms. Lacunar tonsillitis occasionally follows intra-nasal cauterisation; I have seen it in one or two cases of my own, and numerous instances are to be found recorded in the various special journals. The *rôle* played by the tonsils as a point of entrance of germs into the system is now becoming more generally recognised. Gerhardt has termed the tonsil a physiological wound—an inlet guarded, however, by leucocytes which protect the system against the entrance of these germs. If from any reason the energy of the leucocytes is diminished or the tonsil is in an unhealthy condition then the germs of diseases—such as scarlet fever, diphtheria, and other infectious diseases—gain access to the system. Tubercle bacilli can probably pass through the tonsils, and, without giving rise to any disturbance in them, may produce tuberculosis of the glands of the neck. Staphylococci, streptococci, and other micro-organisms can also find their way into the system through the tonsils. Adenoid vegetations in the naso-pharynx have a similar action to the tonsils in this respect, and there can be little doubt that one of the beneficial results of Wilhelm Meyer's discovery will be a lessened amount of danger in cases of scarlet fever and diphtheria and especially a great diminution in diseases of the middle ear.

As I have already pointed out, in a large proportion of the infectious diseases the morbific element is conveyed by the air and consequently usually enters the system *viâ* the upper respiratory tract; hence it was to be expected that this region would show signs of irritation. The typical example of this is diphtheria, in which the disease in the first instance is a purely local one, consisting of a fibrinous exudation caused by the Klebs-Löffler bacillus, and it is not until the toxins produced by these bacilli in their growth have been absorbed that we have constitutional symptoms. Most of the infectious diseases give rise to a catarrhal condition of the air passages. This is especially the case in

[1] Lectures II. and III. will be delivered on Feb. 15th and March 1st respectively.

Hosted by Google

measles. In some the engorgement of the nasal mucous membrane finds relief in epistaxis, so common a prodromal symptom in enteric fever. The naso-pharynx may be the starting-point of some diseases; notably, I believe, is this the case in influenza. I have already discussed the *rôle* of the faucial tonsils as the starting-point of scarlet fever, diphtheria, &c. The larynx deserves special attention in diphtheria, small-pox, and enteric fever. And, lastly, it should be remembered that all diseased conditions of the mucous membrane of the nose, naso-pharynx, pharynx, and larynx, whether merely local as an abraded surface, or as a part of a general disease such as scarlet fever, are liable to be accompanied by a secondary diphtheritic inflammation, and that this is a very grave complication, especially in the case of the acute specific fevers. I will now proceed to describe at greater length the changes seen in the nose and throat as a result of the acute infectious diseases.

SMALL-POX.

This disease is occasionally ushered in with catarrhal symptoms—e.g., sneezing, epistaxis, intolerance of light, lacrymation, sore-throat with redness and some swelling of the palate and tonsils, and hoarseness, symptoms which it is important to emphasise, as they may cause the disease to be mistaken for measles. In the malignant form of small-pox there may be profuse epistaxis. The pustules of small-pox have been seen in the nostrils, mouth, pharynx, and larynx, they have even been noticed as low down as the bronchia of the second or third order. The eruption may occur on any part of the mouth; salivation is present and is very severe in the confluent form of the disease.[2] If the soft palate is affected there is usually much inflammatory swelling and an abscess sometimes results. Owing to the moisture of the mouth the pocks seldom form well-marked pustules. At first they appear as whitish-grey slightly elevated spots, which soon soften and form superficial ulcerations surrounded by a red zone. The larynx in small-pox may be the seat of an inflammatory process causing congestion of the mucous membrane, or there may be a papular or pustular eruption giving rise to but little discomfort. In severe cases, however, about from the ninth to the twelfth day great swelling of the laryngeal mucous membrane may occur, and suffocative attacks due to œdema of the epiglottis and ary-epiglottic folds come on. Trousseau records three cases in which the progress of the disease was so rapid that death occurred before relief could be obtained. In a case of hæmorrhagic small-pox Morell Mackenzie[3] found "ecchymotic spots on the under surface of the epiglottis and on the mucous membrane over the arytenoid cartilages," and Gevaert[4] has described a case of sub-mucous hæmorrhage in the ary-epiglottic folds forming two thick sacs and considerably interfering with access to the larynx. In some cases ulceration extends down to the cartilages causing necrosis, and death may result from impaction of a piece of extruded cartilage in the glottis; or, owing to more or less destruction of the framework of the larynx and cicatricial contraction, stenosis may occur even after the lapse of many years. I knew one patient in whom tracheotomy had to be performed thirty-eight years after the attack of small-pox, and during the whole of this period she was the subject of a chronic laryngeal affection. If the crico-arytenoid joint becomes involved in the inflammatory mischief ankylosis may occur, and the patient will recover with a permanently fixed cord; this condition, rather than paralysis, is probably the explanation of two cases described by Morell Mackenzie[5] in which he says permanent paralysis of the adductor of a vocal cord followed small-pox. As in the other acute specific diseases, the excoriated condition of the mucous membrane of the upper air passages renders it vulnerable to the bacillus of diphtheria, hence a diphtheritic exudation may appear on the fauces, or the patient may have the signs of a membranous laryngitis. This form of laryngeal affection usually begins about the tenth day and runs a rapid and fatal course. Fortunately it is a rare complication. Dr. Ricketts, medical superintendent of the Small-pox Hospital Ships, Metropolitan Asylums Board, writes to me: "I remember only two cases which I regarded as diphtheria (in about 5000 cases). In a few more I have seen some membranous exudation on the fauces. But I have in no case made a bacteriological examination. In fact, the cases I speak of occurred some little time back, before I had the means of making such an examination."

VARICELLA.

According to M. Rondot[6] varicella is often accompanied by a mild sore throat, and he has been able to verify the existence of a varicellous eruption on the buccal mucous membrane even in the absence of a cutaneous manifestation. In this case the diagnosis is based on the objective character of the ulceration of the mouth, on the concomitant sore-throat, and the presence of an epidemic of varicella. Whatever may be thought of a varicellous eruption limited to the mouth there is no doubt that in typical cases of varicella vesicles with reddened bases may be seen on the palate; on the lips, tongue, and cheeks, small round, superficial ulcers occur, seemingly the result of the breaking down of a vesicle—in other words, the eruption of varicella may occur on mucous membranes as well as on the skin. I would lay stress on this point, as Osler and some other writers do not mention the possible occurrence of the buccal eruption. Varicella resembles small-pox inasmuch as the eruption may occur, though very rarely, in the larynx. Marfan and Hallé[7] report two cases. The first case, a child aged three years, was admitted into hospital on account of suffocative attacks. In spite of the absence of a membrane antitoxin was injected. Bacteriological examination, however, showed the absence of the bacilli of diphtheria. Tracheotomy was necessary and the eruption of varicella was then seen. The patient recovered. In the second case the child died from broncho-pneumonia and ulceration of the vocal cords was found.

MEASLES.

The sneezing and running from the nose which are the earliest premonitory symptoms of measles indicate the existence of an acute nasal catarrh. The discharge is at first clear and watery, but soon becomes muco-purulent and often excoriates the upper lip. As a rule the nasal catarrh disappears with the decline of the rash, but under unfavourable hygienic conditions in badly nourished children the discharge may continue and be the commencement of a chronic purulent rhinitis. Epistaxis may occur in the prodromal stage of measles, and in rare cases the loss of blood may be so great as to threaten life. According to Wolff[8] the accessory cavities of the nose are always affected in measles, sometimes with catarrhal inflammation, at others with purulent. This statement must, however, be received with a considerable amount of caution, especially with regard to purulent inflammation, in view of the rarity of acute affections of the nasal sinuses. On the second or third day of the disease hyperæmia of the roof of the mouth and soft palate is to be seen, followed by an eruption of small red points or patches giving a stippled redness to the parts. The term "endanthem" has been applied to this appearance. Inasmuch as this eruption is almost invariably present, and as it precedes the rash on the skin, it is of diagnostic importance where there is an unusually prolonged prodromal stage and in dark races of mankind in whom it is very difficult to recognise the cutaneous eruption. In delicate children severe stomatitis and even cancrum oris may develop; I remember Dr. Gee impressing on me when a student that measles was the most common cause of cancrum oris. The prognosis in these cases is very grave. The tonsils and mucous membrane of the pharynx generally are inflamed and swollen; the inflammatory mischief occasionally spreads up the Eustachian tube and gives rise to earache or even otitis media, but the latter is very rare in comparison to what happens in scarlet fever. Catarrh of the larynx is as much a part of the disease as nasal catarrh. The hoarseness and constant, irritable cough, which are so frequently met with in the first stage of the disease, point to the implication of the larynx. Von Ziemssen[9] speaks of having repeatedly seen a deep uniform redness of the laryngeal mucous membrane, with a yellow-reddish colour of the vocal cords. In rare cases measles comes on with the symptoms of laryngeal obstruction, and as the rash comes out these subside. Owing to the tendency to spasm in children the cough is not infrequently of a croupy nature. In the severe forms of laryngitis ulceration of the mucous membrane and even an abscess may occur, or death may in rare cases be due to œdema of the larynx. Dr. Major[10] of

Montreal has recorded a case of complete aphonia without the slightest embarrassment of respiration coming on during an attack of measles of more than usual severity. On laryngoscopic examination the left arytenoid was found fixed at full inspiration and completely immovable. There was redness about the joint and external tenderness. The larynx was otherwise normal.

Membranous laryngitis is an infrequent but very dangerous complication of measles. According to Morell Mackenzie [11] it is even more fatal than the corresponding scarlatinal affection, 80 per cent. of the cases proving fatal. This complication is, in the majority of cases, true diphtheria. "It usually supervenes during the eruptive stage, often just when the rash is fading; sometimes it arises later. The symptoms of laryngeal obstruction develop with great rapidity and are accompanied by a rise of temperature." [12] Dr. H. Smith [13] has recorded the occurrence of three cases of paralysis of the intrinsic muscles of the larynx. The paralysis set in within a few days after the subsidence of the fever. Loss of phonation was the only symptom. There was no congestion or inflammation of the larynx present. The first case lasted about ten days (without any treatment). The second and third cases lasted about six days treated with strychnine. I have seen aphonia due to paresis of the thyro-arytenoid muscles coming on after measles and cured by strychnine and faradaisation.

RÖTHELN: GERMAN MEASLES.

In this disease there is frequently slight nasal catarrh, but not to be compared to what is met with in measles. A sore-throat which resembles the early stage of the scarlatinal sore-throat is usually present; indeed, it was on this account that rötheln was originally regarded as a hybrid between scarlet fever and measles—i.e., it was said to have the sore-throat of scarlet fever and the rash of measles. As a rule there is only a moderate amount of injection of the throat, with some swelling of the tonsils; there is hardly ever any ulceration and never any sloughing. I would insist on the constancy of sore-throat as a symptom of German measles, as Osler in his otherwise admirable text-book on medicine makes no mention of its occurrence.

SCARLET FEVER.

One of the most important of the recent advances in the treatment of infectious diseases is the attention directed to the condition of the nose and naso-pharynx. In no disease is this more necessary than in scarlet fever. In severe forms of this disease the nostrils and naso-pharynx may become affected by extension from the pharynx. The Eustachian tubes opening into the naso-pharynx participate in the inflammatory mischief, which spreading up the tubes gives rise to otitis media and all the dangers to life and hearing therewith connected. At the commencement there may be noticed a catarrhal condition of the nasal mucous membrane, but the discharge rapidly becomes muco-purulent and very acrid, so that it excoriates the upper lip. In cases of a malignant type the mucous membrane may slough in places, and necrosis of bone and cartilage may result. In scarlet fever the streptococci of pus develop in great numbers in the mucous discharge; cervical adenitis and abscess, purulent otitis media, endocarditis, pleurisy, &c., are due to their absorption; hence the importance of local treatment.[14] In some cases epistaxis occurs at the commencement of the disease; when it occurs towards the end or during convalescence it is to be attributed rather to the kidney condition than to the fever. If a nasal discharge comes on during convalescence the secretion should be submitted to bacteriological examination, as post-scarlatinal diphtheria may attack the nasal passages primarily or exclusively. As in measles, the accessory sinuses, according to Wolff,[15] are always affected, the inflammation being sometimes of a catarrhal nature; in other cases suppuration may occur. I have already expressed my doubts as to the constant affection of the sinuses in measles, and I would repeat them again in respect to scarlet fever. It is quite unnecessary for me in this assembly to enter upon a description of the condition of the throat in scarlet fever. In passing, however, I should like to direct your attention to a very important practical point which, I think, is often overlooked, resulting in the occurrence of preventable disease and death. I cannot do better than quote Dr. Dukes, the able physician to Rugby School: "There is a class of sore-throats—to all appearance often only simple acute tonsillitis, while at others having a membranous or sloughy appearance and with a complete absence of eruption on the skin—occurring in those who have already had scarlatina. This kind of sore-throat, however, is capable of passing on scarlatina to an individual who has not already been affected by it. Scarlatina is often spread extensively by this means; for, if the patient has suffered previously from scarlatina, these sore-throats are looked upon as simple non-infectious sore-throats, and are consequently not carefully isolated for three or four days as they should be." [16] The occurrence of a membranous inflammation of the throat during the course of scarlet fever has attracted much attention of late years. It is now pretty generally agreed that a membrane may present itself at two periods of the disease [17]—(1) during the acute stage—i.e., during the period of eruption; (2) during convalescence or even later. 1. The membrane which occurs in the first period, though it may be whitish-grey, thick and adherent, and to the naked eye hardly at all to be distinguished from a true diphtheritic membrane, is proved by bacteriological examination to be due to streptococci and not to contain the Klebs-Löffler bacillus. It may also be distinguished clinically from diphtheria by not speading to the larynx and by not recurring locally. Dr. Sidney Martin [18] suggests that the throat already attacked by scarlet fever poison is rendered less capable of resisting the invasion of other organisms. 2. The membrane met with in the second period contains the Klebs-Löffler bacillus, and as this is accompanied by the presence of streptococci the disease represents a very grave combination. It is, of course, possible that diphtheria may occur as a complication of scarlet fever during the early stage, but this is, according to Dr. Washbourn,[19] a very rare mishap; the only way of arriving at a correct diagnosis is a bacteriological examination. As regards the method of infection, Dr. Goodall [20] is of opinion that the introduction of diphtheria into the Asylums Board's fever hospitals is generally due to infection from mild cases of that disease inadvertently admitted as scarlet fever. He thinks that the susceptibility of scarlet fever patients to the infection of diphtheria has been greatly exaggerated, for the great majority of those exposed to it in the observation ward, when the diagnosis was clinical only, did not contract it. It would appear that scarlet fever alone is not the predisposing cause to this mixed infection. According to Dr. Goodall "the prevalence of post-scarlatinal diphtheria has closely followed that of the primary form, and its incidence had not been materially higher among the scarlet fever patients in the hospitals than among the juvenile population of the metropolis of like ages." This would seem to suggest that an entrance for the diphtheritic bacillus is facilitated by the presence of some other organisms, possibly streptococci. Laryngeal mischief in connexion with scarlet fever apart from diphtheria is rare. Dr. Washbourn,[21] however, states that he has seen cases of ulceration of the larynx in scarlet fever unaccompanied by membranous exudation. Mr. Pepper [22] has recorded a case, of which the heading of the paper he read before the Clinical Society gives an epitome: "Scarlet fever; secondary sore-throat on fifty-fourth day; severe bleeding on fifty-eighth; ligature of left common carotid on fifty-ninth; hoarseness, followed by sudden aphonia, on same day as hæmorrhage; bursting of retro-pharyngeal abscess after application of ligature; recovery, with fixation of left vocal cord." In reference to the laryngeal condition, Mr. Pepper writes: "The sudden change in the voice from huskiness to complete aphonia came on prior to the operation and must have been due either to œdema of the mucous membrane of the larynx or to stretching of the vagus nerve from the extensive extravasation into the tissues of the neck." Dr. Mahomed examined the patient when he was convalescent and reported that the left cord was still almost completely fixed, and added, "Whether this fixation is due to paralysis or to inflammatory swelling I am by no means certain; I am inclined to think the latter." To me the history of the case clearly points to

inflammatory mischief in the neighbourhood of the left crico-arytenoid joint, causing arthritis and subsequent ankylosis of this joint. Gevaert[23] of Ghent mentions a case of scarlatinal angina in which, on account of stenosis of the larynx and threatened asphyxia, tracheotomy had to be performed.

WHOOPING-COUGH.

Whooping-cough almost invariably begins with a catarrhal stage, the nasal mucous membrane sharing in the catarrhal condition. During the paroxysmal stage epistaxis is a common symptom, and so far from being a grave one it often seems to relieve the patient. There is a difference of opinion as to whether there are any constant changes to be seen in the larynx during life. Von Herff,[24] while suffering from an attack, made a series of examinations upon his own larynx. He noted in the first stage a slight catarrh of the larynx, which became very intense during the spasmodic stage; the vocal cords, however, were not affected. The hyperæmia extended into the trachea. During every paroxysm a pellet of mucus could be seen on the posterior wall of the larynx on a level with the glottis; when this was expelled the attack ceased.

INFLUENZA.

Influenza is essentially a catarrhal disease—that is to say, the micro-organism, almost certainly that described by Pfeiffer, seems to attack the mucous membrane in the first instance; in some cases its effects are almost confined to them, and in nearly every case they experience the chief brunt of the disease. Very curiously Landgraf[25] states that he has seen rhinitis only once in 216 cases of influenza. He adds that this is the more surprising as in text-books it is reckoned as one of the most common symptoms of influenza. The only explanation that seems forthcoming is that Landgraf would not class a catarrhal state of the nose as rhinitis, but reserves the latter for severe inflammatory condition of the nose. The nose, as being the chief portal of the entrance of the specific bacillus, which is taken in with the inspired air, is early affected, and the excessive sneezing, marked interference with nasal respiration, and profuse running from the nose testify to the violence of the attack. In many cases the acuteness of the catarrh causes a certain amount of hæmorrhage from the nose. Occasionally this has been of an alarming nature, the bleeding occurring from the posterior third of the nasal cavity; in some cases, indeed, a special hæmorrhagic tendency seems to have developed during the course of the disease. A frequent sequel of the rhinitis of influenza is some alteration in the sense of smell. Usually it takes the form of simple loss of the sense of smell—anosmia. More rarely the anosmia is accompanied by perverted olfactory sensations—parosmia. I have met with all degrees of anosmia from slight impairment of the sense of smell to its complete loss. As a matter of course the loss of the sensation of smell was accompanied by loss of so much of the sense of taste as depends on flavour. I have no note as to the loss of gustatory sensations. One of my patients was a woman, twenty-eight years of age, who originally consulted me for debility, neuralgia, and violent fits of sneezing. She improved under the administration of iron and arsenic; I did not adopt any local treatment for the nose. In March, 1895, she had a mild attack of influenza which was followed by cessation of the attacks of sneezing, but she lost her sense of smell. The latter has persisted up to the present in spite of treatment. This case would seem to suggest that the inflammatory condition of the nasal mucosa led to changes both in the filaments of the fifth nerve in the nose and also to those of the olfactory, in the one case abolishing the hyperæsthesia and thus stopping the sneezing, and in the other case annihilating the normal sensibility of the nerve and causing anosmia. The accessory cavities of the nose are very liable to be affected in influenza, the intense frontal headache being due in many cases to extension of the catarrhal process from the nose to the frontal sinuses. In one patient under my care the pain and feeling of weight and fulness persisted so long after the influenzal attack that I thought it would have been necessary to adopt surgical measures to obtain relief; the patient, however, recovered without operation. Dr. Felix Semon[26] has narrated his personal experience of acute inflammation of the left antrum of Highmore after influenza, and many similar cases have been recorded. Cases of antral disease coming on in this acute manner respond much more quickly to treatment than those developing more gradually. In many cases the influenzal attack begins with symptoms referred to the naso-pharyngeal space, and it appears to be the starting-point of a large number of local affections coming on during influenza, notably otitis media and its result, and it may be the centre of the systemic infection. The patient complains of severe headache extending to the back, difficulty in breathing through the nose, and the sensation of a foreign body, variously referred to the nose or throat, so that the patient is constantly hawking or trying to clear the throat. On making a rhinoscopic examination the mucous membrane of the naso-pharynx will be found much swollen and covered in places with a viscid secretion; in exceptional cases I have seen follicular inflammation of the pharyngeal tonsil. Shelley[27] has called attention to the existence of a vesicular eruption on the palate as a sign of influenza. Acute pharyngeal catarrh is a very common condition in influenza; the mucous membrane is of a purplish colour and œdematous, and in consequence of the swelling and the muscular infiltration pain and difficulty in swallowing usually exist. The faucial tonsils, like the pharyngeal, may be the seat of follicular inflammation with or without peri-tonsillar mischief; they may be covered with a pultaceous exudation. On more than one occasion I have seen influenza start in a household with one inmate being attacked with what was apparently an ordinary lacunar tonsillitis, and it was only the fact of other members of the family speedily succumbing to one of the more ordinary varieties of influenza that cleared up the diagnosis in the first case. Occasionally the inflammatory mischief runs a very severe course. In one patient I saw in consultation with Dr. Penny the condition was that of a phlegmonous pharyngitis, as there was great swelling of the pharynx followed by suppuration, and the urine contained much albumin. This patient recovered. In two other cases a membranous exudation formed on the soft palate. It resembled in some respects a diphtheritic membrane, but unfortunately in neither case was a bacteriological examination made. In both patients the urine was albuminous. Both these patients died. One of the most common of the complications of influenza is laryngitis of all degrees of severity. In the mildest cases the larynx is seen to be the seat of a slight catarrh, the symptoms being a troublesome, irritable cough, difficult to cure, with hoarseness or even loss of voice. In more severe cases the vocal cords are intensely injected, the sputa may be tinged with blood, and occasionally the expectoration of blood has been so profuse as to warrant the term of hæmorrhagic laryngitis being applied. As I have already stated when speaking of influenzal epistaxis, a hæmorrhagic tendency is distinctly developed in some cases of influenza. The presence of dysphagia is said to differentiate the hæmorrhagic laryngitis of influenza from the ordinary forms of hæmorrhagic laryngitis. This statement requires confirmation.[28] Several authorities have noted infra-glottic swelling in cases of influenzal laryngitis. Fraenkel[29] regards as characteristic of this disease a fibrinous infiltration of the vocal cords, giving a whitish appearance in places to the cord. This is followed by a superficial loss of epithelium. Ulceration of the vocal cords, apart from any fibrinous exudation, has been described in influenza. The ulcers are quite superficial, occur in the anterior part of the cords, and usually heal rapidly. In severe cases swelling of the ary-epiglottic folds, occasionally amounting to œdema of the larynx, has been noted. Abscess of the larynx has been met with as a complication of influenza. Schaeffer[30] records a case in which abscesses developed in three different parts of the larynx; tracheotomy was required on account of dyspnœa, the cannula was able to be removed after eight days, and the patient made a good recovery.

The most common paralytic affection of the muscles of the larynx met with in influenza is paralysis of the adductors and tensors of the cords, giving rise to loss of voice. Lublinski[31] has recorded one case of paralysis of the posterior crico-arytenoid on the left side which recovered in the fourth week, and I have seen bilateral abductor paralysis

follow a severe attack of influenza. Kuttner[32] showed at the Berlin Laryngological Society a woman, fifty-four years of age, who had during an attack of influenza paresis of the soft palate and muscles of the posterior wall of the pharynx on the left side and paralysis of the corresponding cord. He regarded it as a case of recurrent paralysis of neuritic origin.

ENTERIC FEVER.

In enteric fever there is a tendency to a catarrhal state of the mucous membranes, and the pituitary membrane suffers with the others. Two symptoms met with in enteric fever are due to the catarrh of the nose—viz., the deafness which results from extension of the catarrhal process to the Eustachian tubes and their consequent occlusion, and epistaxis. Epistaxis is so common a symptom at the commencement of enteric fever that, given a young adult who is feverish and has had an attack of nose bleeding, the possibility of enteric fever should be borne in mind. Epistaxis is most frequent in the first week of typhoid fever, on the second or third day. As a rule it is of no prognostic significance, but occasionally the loss of blood has been so excessive as to destroy life. Devic[33] states that buccal ulceration is fairly common in enteric fever. The ulceration is always superficial, oval or round in shape, with regular and not undermined margins. It occurs most frequently on the anterior pillars of the fauces. The lateral aspect of the tongue, the anterior surface of the soft palate, and, lastly, the tip of the tongue come next in order of frequency. The ulcers may be red or yellowish-red, and are frequently covered with mucus, but a false membrane never occurs. As there are usually no symptoms the ulceration must be specially looked for in order to be recognised. According to Tripier these ulcers run an absolutely parallel course with the intestinal lesion; he therefore considers them of great value as a guide to the condition of the intestines. Devic has been able in three cases to predict a relapse owing to the fact that, though the patient had improved and the temperature was lower, there was no attempt at cicatrisation of the buccal ulceration. He has met with this condition in about one-sixth of the cases of enteric fever; they do not in themselves affect the prognosis. They are best treated by mild antiseptic lotions; caustics are unnecessary. At the commencement of enteric fever there may be some erythema of the pharynx and enlargement of the tonsils, but there is nothing characteristic. Dr. Gee[34] says: "Sore-throat attends the first few days of typhoid fever with a frequency which is remarkable. Hereby for a time perplexities in diagnosis may occur." He regards it as a necessary part of the febrile state rather than a symptom of the specific fever. Ulceration of the pharynx has been noted in exceptional cases. According to Morell Mackenzie[35] an herpetic eruption is occasionally seen on the mucous membrane of the pharynx and mouth, accompanied by pain in deglutition. As in the other acute specific diseases, a secondary diphtheritic deposit may occur on the fauces of patients suffering from typhoid fever. It usually occurs during the third week, and is a serious and fatal, but fortunately rare, complication. Out of six cases mentioned by Oulmont five terminated in death, and Peter states that it has been fatal in all the instances he has met with.[36] Clinically, the laryngeal changes in typhoid fever may be considered according as to whether they occur as a complication of the fever or whether the symptoms they present are so severe as to mask the underlying disease. Of the first variety laryngitis is the representative; a mild form, characterised by slight injection of the larynx and increased cell proliferation, is fairly common in the second and third weeks of the disease. Landgraf[37] has several times seen yellow patches in the larynx formed by colonies of staphylococcus pyogenes. A more severe form may occur acutely during the third week of the fever, or it may show itself in a chronic form during convalescence. During the first two weeks of typhoid fever there is often reason to suspect a catarrhal condition of the larynx from the patient's voice and the signs of catarrh of throat and chest, but it is usually not until the third week that the severe symptoms present themselves. These are hoarseness and feebleness of voice, dyspnœa (chiefly affecting inspiration, expiration being easy), and pain and difficulty in swallowing. Laryngoscopic examination is naturally difficult in patients in the third or fourth week of typhoid fever, but if practicable swelling of the arytenoids and of the ary-epiglottic folds and some ulceration are the conditions most likely to be recognised. Tracheotomy is generally necessary on account of the increasing dyspnœa. Death may be due to a laryngeal ulcer spreading down into the connective tissue and giving rise to subcutaneous emphysema. Fagge and Pye-Smith mention cases of this sort recorded by Wilks and Ziemssen. There is an interesting case reported by Dr. Parsons,[38] in which the emphysema occurred after tracheotomy had been performed, death following about fourteen hours later. At the post-mortem examination œdema of the larynx or purulent infiltration of the mucosa, together with more or less chondritis, are generally found. The chronic variety most frequently occurs during convalescence, or it may not be noticed until recovery is apparently complete. The patient presents the usual signs of laryngeal stenosis; sudden death may be caused by œdema of the larynx or impaction of a portion of necrosed cartilage in the glottis. If the urgency of the dyspnœa necessitates tracheotomy the cannula has generally to be worn permanently, as destruction of the cartilage leads to collapse of the larynx. Even if recovery takes place without tracheotomy, trouble in connexion with the voice and breathing may result from the cicatrisation of the ulcerated parts. I have recently had under my care a man who suffered from typhoid fever with laryngeal complication in 1856. In this case the ventricular bands were thickened, the left vocal cord was immobile in the cadaveric position, and there was thickening about the crico-arytenoid joint, and the outward movement of the right vocal cord was somewhat interfered with, but as the cord crossed the median line it came nearly in contact with its fellow, so that the voice, though feeble, was fairly clear. There was no dyspnœa except on great exertion. This was an example of how good a recovery may ensue even in a severe form of typhoid laryngeal mischief.

I now propose to describe another class of cases to which the name of laryngo-typhoid has been applied in which the poison of typhoid fever is at the onset focussed, as it were, upon the larynx, so that the symptoms of the local affection may, up to the end of the first week, so completely mask the underlying febrile state that it is not until the appearance of the eruption and other characteristic symptoms of typhoid fever that the diagnosis can be made with any degree of certainty. A typical case is one recorded by Gerhardt.[39] A man, aged eighteen years, "has been subject to hoarseness and cough with the slightest colds. On Dec. 24th, 1877, he was exposed to severe cold and wet. This was followed by severe chills, fever, pain in the throat, and cough with mucous expectoration. The voice was affected immediately; soon he became hoarser; when he entered the hospital he was completely aphonic. In swallowing there was severe, and on attempting to speak slight, pain in the throat. From the first he had headache, dizziness, and debility, soon after also hardness of hearing. On the 28th he took to his bed. The nights were restless and disturbed by dreams. On Jan. 1st, 1878, several copious bleedings from the nose occurred. On the 2nd he entered the hospital with fully developed symptoms of typhoid fever, particularly enlargement of the spleen, and the characteristic roseolar eruption." The laryngoscopic examination revealed swelling and injection of the epiglottis with an extravasation of blood the size of a pin's head. The laryngeal mucous membrane generally was in a similar condition, and there were dark extravasations of blood over the vocal processes. The neighbouring lymphatic glands were swollen and tender. Ulcers eventually formed on the epiglottis and arytenoid cartilages. The fever ran a normal though severe course. The patient left the hospital on Feb. 13th with a good voice; the ulcers were entirely cicatrised, and strength was completely restored. A series of five cases reported by Dr. Watson Williams[40] is important as pointing to the possibility of typhoid fever being communicated by the breath. This method of communication is, of course, most likely to occur in cases af laryngo-typhoid, hence special prophylactic precautions should be taken in these cases. Patients

with any previous tendency to laryngeal affections seem to be more vulnerable to this form of typhoid fever than others; this was the case in Gerhardt's patient, and also in Dr. Watson Williams's first patient.

Shortly after writing the above a man, aged forty-five years, was admitted under my care into the Westminster Hospital from the throat department. On admission his temperature was 99 4° F. and rose the same evening to 103°. The nasal mucous membrane was dry and covered with crusts, the vocal cords were much congested, thickened, and irregular, and covered with inspissated mucus. The patient had a cough, was very hoarse, and appeared much more ill than the local condition would account for. In the course of a few days I came to the conclusion that I had to deal with a case of laryngo-typhoid, and the subsequent course of the disease verified my diagnosis.

Œdema of the larynx may occur as a result of any of the laryngeal complications of typhoid fever; it has been the cause of death in a case of ambulatory typhoid fever, without any previous symptoms of throat mischief.[41] Paralysis of the vocal cords is occasionally seen as the result of enteric fever. Lublinski,[42] for example, has seen five cases, four in men and one in a woman, all occurring between the ages of twenty-seven and thirty-nine years. In one case there was bilateral abductor paralysis, in three paralysis of one recurrent nerve, and in one paralysis of both recurrent nerves. The paralysis may be due to pressure on the recurrent nerve by enlarged glands or thickened pleura; or, inasmuch as it is sometimes accompanied by paraplegia or paralysis of peripheral nerves, we must assume the existence of an anterior poliomyelitis or a peripheral neuritis due to toxins. The symptoms usually show themselves during defervescence. Of the five cases recorded by Lublinski, one case, that of bilateral recurrent paralysis, died three days after the onset of the paralysis. In the case of bilateral posticus paralysis tracheotomy had to be performed. The diagnosis in these cases is only to be made by means of the laryngeal mirror, and care must be taken to exclude cases of fixation of the vocal cord due to ankylosis of the crico-arytenoid joint. The most recent account of the pathology of the laryngeal complications of typhoid fever is that contained in the paper written by Dr. Kanthack and Dr. Drysdale and the discussion thereon at the Laryngological Society of London on Feb. 12th, 1896. The paper was based on the post-mortem records of sixty-one cases. In fourteen there was loss of substance in the larynx and in eight it was stated in the post-mortem books that the larynx had not been examined, so that, assuming that the larynx had been examined in all the remaining 53 cases, which is doubtful, ulceration was found in 26 per cent. of the fatal cases. This represents a great advance in numbers affected compared with Hoffmann's figures, as quoted by Fagge and Pye-Smith;[43] he gives only 28 cases of ulceration in 250 necropsies—i.e., a percentage of 11 as against 26. One explanation is that the larynx of late years has been more carefully investigated than formerly, and another is that Dr. Kanthack and Dr. Drysdale included slight losses of substance in their list, whereas Hoffmann only reported cases of distinct ulceration. According to Dr. Kanthack and Dr. Drysdale the ulceration is most frequently seen over the tip and edges of the epiglottis and in the neighbourhood of the processus vocalis. Various explanations have been given as to the pathological nature of these lesions. Dittrich assumed that they were of decubital origin; the evidence on this point is conflicting. Rokitansky pronounced in favour of the typhogenetic nature of the ulceration, but clinical evidence and the results of recent bacteriological examination tell rather against this theory. I am myself inclined to agree with Dr. Kanthack and Dr. Drysdale in their summary of the question: "The evidence in their possession convinces them that these laryngeal ulcers occurring during the course of typhoid fever are caused by fresh infections with pyogenic organisms which always abound in the larynx and which gain a firm foothold on the debilitated tissues, although they cannot deny that in an individual case the typhoid bacillus may have escaped and caused the lesion." Dr. Jobson Horne made an important remark during the discussion to the effect that in some of the larynges of persons dying from typhoid fever the ulceration had been proved by microscopical examination to be of a tuberculous nature. From this he deduced two conclusions: (1) that typhoid fever may be a possible factor in the etiology of tuberculous ulceration of the larynx; and (2) that the tuberculous diathesis may be a factor in the etiology of typhoid ulceration of the larynx. One of the most characteristic features of the typhoid affection of the larynx is the tendency to suppuration about the cartilages leading to their necrosis and extrusion and the tendency to destructive changes in and about the crico-arytenoid joints, so that if the patient recovers he does so with an immobile joint and consequently fixed cord. Lacoarret,[44] in an excellent article on Arthritis of the Crico-arytenoid Joint, has collected many examples of this condition occurring as a result of enteric fever.

ERYSIPELAS.

In the production of facial erysipelas chronic nasal affections play an important *rôle*, hence the frequency with which erysipelas starts from the centre of the face, the orifice of the nostril being a favourite point of departure. A large amount of literature has accumulated on the subject of erysipelas of the pharynx and larynx, but our ideas on this subject have been clarified since we recognised the streptococcus erysipelatis as the cause of erysipelas. If, as seems likely to be the case, the streptococcus pyogenes, the cause of various septic affections such as phlegmonous erysipelas, is proved to be identical with the streptococcus erysipelatis, the whole subject of erysipelas of the throat will be much simplified. I am strongly in favour of the view propounded by Dr. Semon, that erysipelas, phlegmonous pharyngitis, angina Ludovici, and similar conditions are only modifications of the same process, differing in their virulence or place of development. I have discussed the subject of erysipelas of the pharynx and larynx in a paper presented at the meeting of the British Medical Association in 1891,[45] so that it is unnecessary for me to say more on the subject on the present occasion.

ABSTRACT OF

An Address

Delivered to the Surgeons on Probation at the Termination of the Seventy-third Session of the Army Medical School, Netley,

BY SURGEON-MAJOR-GENERAL J. JAMESON, M.D. GLASG.,

DIRECTOR-GENERAL, ARMY MEDICAL DEPARTMENT.

[SURGEON-MAJOR-GENERAL JAMESON began his address by dwelling upon the advantages which accrue from the Services as a factor in education, and referred to the different conditions of life in the Services at a time when £1000 were paid for an exchange to India to obtain a shake of the Pagoda tree and in the present day. Dealing with the regimental system, he said it was still a question unsettled whether the abolition of that system was a benefit or a misfortune. Considered from an administrative point of view, there could be no doubt of the advantages of unification, although it had to be confessed that 99 per cent. of military officers did not acknowledge them. This, in his opinion, was the main reason why the success of the new system was not the better assured. Continuing, he said:—]

There is a habit of some, and a vile habit it is, of expressing grievances and other matters anonymously in the public press. A wrong diagnosis, faulty treatment, doubtful administration, or what appears to be such, are examples of subjects which have received public criticism. It is painful to relate, but true all the same, that of all branches of the service the officers of the Army Medical Staff, and particularly the retired ones, are the greatest offenders in this respect. The Naval Medical and the Indian Medical Services are comparatively innocent. We often ask that the Army Medical Service should be constituted on the lines of the Royal Engineers. Would that we followed the lines of

Hosted by Google

the Royal Engineers in being loyal to each other. Does an officer of the Royal Engineers never make a mistake; but who ever heard of an inward scandal in his corps? If any man have a grievance let him seek redress through his own commanding officers; a favour to ask, let him ask it through the legitimate channels with a certainty as regards myself. The giving is always more agreeable than refusing. Giving may not always be possible, nor does a refusal necessarily mean an injustice, and when the refusal is followed by an appeal to a military, medical, or society journal the wisdom of refusal becomes apparent. Let us suppose that the Indian pay is increased, the period of the Indian tour shortened, perhaps the home tour lengthened, leave for study allowed, presidency or membership of mixed boards a right, messes in large stations established with a Government grant, badges of rank fully recognised, even army titles conceded, and a corps of royal surgeons formed. Is that enough? No; they are all as sounding brass and tinkling cymbals unless one thing more is possessed—professional merit. And here we are back to the good doctor again, for we cannot do without him. Your duty is to attend to the sick and wounded soldier and to prevent disease. To do that efficiently and at the same time to maintain self-respect in the performance, perfect equality with all branches of the service, save in the right of military command, is essential, and for that reason only is it claimed. I am glad to observe that the subject of the Army Medical Department is exciting attention outside military and medical journals. In *Blackwood's Magazine* of December last there is an article on the subject full of historical interest and instruction which will be read wherever English literature is appreciated. It is an education for the public, who will now be able to understand better the complicated nature of our duties in peace and war. The value of the article is enhanced by the fact that the writer is a general officer of distinction and experience, and it is an indication that the military portions of our duties are being recognised. Modern warfare has greatly changed the situation, and war risks are now pretty evenly divided amongst all ranks. Indeed, according to Mr. Archibald Forbes—no mean authority—the Medical Staff and Corps present are likely to be annihilated at the first general engagement. This possibly is an over-gloomy view of the situation, but probably when once in action and in range it is better to go on than to stop. The difficulty will be to get on when so many wounded are calling for assistance. The battle over, the warrior rests, eats, drinks, and sleeps. What of the medical officer? No rest for him that night, and he is fortunate who has had the forethought to provide himself with a sausage and a bit of bread. For him there is the long, weary night of anxious thought and downright hard work—dressing, operating, and giving chloroform in turn, his back aching, his fingers paralysed with fatigue as he compresses the severed artery, his face and clothes bespattered with blood. Complications are ever arising: now an exhausted patient to be succoured, there a case of secondary hæmorrhage to be attended to, necessitating the undoing of the dressings and fresh ligatures to the vessels, and so the night passes and morning still finds him alongside his patient, and he is lucky if the work is all done. Also on the march—in sun, rain, or snow—he shares with his military brother fatigue and privation, and here again the end of the march is the beginning of his hard medical duties. Risks of war, indeed! Who have the risks? The medical officer shares every one, *plus* those belonging to his profession. We hear little of caste prejudices on active service. As for rewards, that is another story; but I, with great satisfaction, may allude to the gazettes which followed the last Ashanti and Soudan expeditions in proof of a fairer and more liberal spirit now existing.

The Indian Medical Service provides employment of a very varied character for its members, thus giving scope for the exercise of a great variety of tastes, gifts, and attainments. The Government of India has always employed its medical officers for whatever duties—military and civil, professional and scientific—their capacity, education, and training have fitted them to perform. The medical charge of Government establishments and institutions is of course the primary object of the recruitment of the service, but the talents and acquirements of Indian medical officers have been utilised for a great many other purposes, such as the charge of prisons and asylums, professorships and lectureships in medical colleges and schools, political and scientific missions and commissions, botanical, chemical, medico-legal, and zoological appointments, special sanitary and vaccination employment, surveys and researches, opium and mint appointments, and so forth. At one time, indeed, the Honourable East India Company's medical officers were actually employed as postmasters and registrars, and when the electric telegraph was introduced into India the organisation of the department was entrusted to a distinguished surgeon, the late Sir Wm. Brook O'Shaughnessy. Under these circumstances it is not surprising that while the service generally has always maintained a high standard of ability, it has produced some very distinguished men who have done very valuable work. The writings of Twining, Annesley, Morshead, Vandyke Carter, Maclean, Fayrer, and Moore will always be treasured as classics in tropical medicine and surgery. Many other names connected with statistics, sanitation, botany, and natural history could be mentioned to swell the list of Indian worthies whose work endures. Through the agency of the Medical Service charitable hospitals and dispensaries have been established throughout the empire, so that medical and surgical relief has been brought within the reach of the people in town and country. The rate of development of these institutions in late years has been marvellous, and perhaps in no other form has the advantages of English influence in India been brought home to the Indian people in a form so admirable.

Since the year 1865 all officers destined for the Indian Medical Service have passed through this school. The fact that the present able and respected head of the Service, Surgeon-Major-General J. Cleghorn, sat on these benches shows that a whole generation of officers who have been *alumni* of the Army Medical School has during these last thirty-one years gradually occupied the places and assumed the duties of the men entertained prior to 1860, of whom very few, if any, remain in India. It is pleasant to be able to state that this new generation of Indian medical officers has fully maintained the honourable traditions of their Service and reflected credit upon the school which delights to watch their career and claim some share in their success. In India the field of labour tends to contraction as the methods of governing the empire become better organised and more stereotyped. Nevertheless, the Service still offers great opportunities of good work and of distinction, and in this connexion I may mention the name of Sir George Robertson, the hero of Chitral. It offers a competency to all and more than a competency to some. Owing to the multiplication of competent indigenous practitioners and the depreciated rupee it is more difficult, perhaps, to amass large fortunes than in the old days. Still, the career before you is full of promise and interest, and that you may enjoy it and prosper in it is the fervent wish, I am sure, of all who are assembled here to-day.

In conclusion, I must refer to the good work done in India and at Netley by Cayley (whose service with the Indian Government began forty years ago) Pringle, Guthrie, McGrigor, Muir, Munro, Crawford, and Mackinnon. You are never likely to forget Parkes and his work at Netley. The hall-mark of the sterling value of Netley was stamped by him, and his disciples and followers, De Chaumont and Notter, had been worthy successors in the great field of hygiene. One name, that of Longmore, who so long held a distinguished connexion with this school, recalls the value of his teaching and the nobility of his character.

[Surgeon-Major-General Jameson finished an interesting address by saying how justly proud they were of the number of occasions on which the decoration of the Victoria Cross had been bestowed upon the officers of the medical department.]

THE EASTERN DISPENSARY, BATH.—HONORARIUM FOR THE MEDICAL OFFICERS.—The Mayor of Bath presided at the annual meeting of this dispensary, held on Jan. 22nd. He mentioned that the institution deserved the very warmest support, as it was doing a most excellent work. The honorary secretary read the report, which showed a satisfactory state of things financially; it stated that during 1896 there were 4437 patients treated at the dispensary and 623 attended at their homes. The dental department reported a further increase of patients. It was agreed, on the proposition of the Rev. B. N. Thompson, to present an honorarium of five guineas to each of the honorary medical officers.

DYSENTERY AND ITS TREATMENT.

WITH AN ACCOUNT OF SIX YEARS' EXPERIENCE IN THE TRANSVAAL AND MATABELELAND IN THE USE OF SOME VARIETIES OF MONSONIA AS THE CURATIVE AGENT.

BY JOHN MABERLY, M.R.C.S. ENG., L.R.C.P. LOND.

WITH the progress of sanitation dysentery has almost disappeared from the British Isles and is now looked upon as a disease peculiar to tropical and semi-tropical climates. It, however, is not necessarily restricted to such geographical limits, various outbreaks having occurred in England and on the continent up to a recent period which appear to have been closely associated with insanitary conditions and more or less malarial atmosphere. It is to the writers of the last thirty or forty years that we are indebted for a more accurate knowledge of the pathology and therapeutics of dysentery, and as far as our own nation is concerned almost entirely to those who have been engaged in medical work in India. Dysentery is described by Joseph Ewart as a specific febrile disease accompanied by considerable nervous prostration and characterised by inflammation of the solitary and tubular glands of the large intestine. It is no doubt due to specific poison, but at present there is great uncertainty as to its exact nature. Bertrand and Baucher in 1893 studied an epidemic among the troops stationed at Cherbourg and arrived at the conclusion that no one of the many micro-organisms found by them could be considered as specific for the disease. Arnaud in 1894 investigated sixty cases of tropical dysentery and arrived at the conclusion that the disease is due to a pathogenic variety of the colon bacillus.

Dysentery is generally most prevalent during the rainy season in tropical and semi-tropical climates, and is confined principally to malarial districts, being often associated with attacks of intermittent or remittent fever. Air contaminated by decayed organic matter may be a factor in causing an outbreak of dysentery, but experience goes to show that bad drinking-water is a more fertile cause of the disease. Two notable instances of the latter came under my notice in South Africa. The first was in 1891 whilst in medical charge of a thirty-mile section of railway in course of construction along the Klip River in the Transvaal. The line was being laid by a number of sub-contractors, whose camps, about fifteen in number, were situated at various points along it. The Kaffirs working at these posts suffered severely from fever and dysentery with the advent of the first heavy rains in September and October, the only exceptions being at one camp situated in low ground, at which about sixty Kaffirs were stationed, where not a single case occurred. The only assignable reason for this exemption appeared to be that the contractor insisted on his Kaffirs drinking water from a well close by instead of the river water, which was contaminated with all sorts of organic refuse washed into it from the surrounding country, which was being used by all the other Kaffirs. Another instance occurred during the Matabele rising in May, 1896. Whilst acting as medical officer to the Bulawayo Field Force I was struck with the number of cases of acute dysentery which occurred among the men in the Bechuanaland Border police camp. On making inquiries I found that they were drinking water from a well which on examination was found to contain a number of dead mice and other refuse. The well was cleaned and disinfected, with the result that the number of cases of dysentery at once diminished.

The symptoms of dysentery are so distinct that it is almost impossible to overlook them or mistake them for those of any other affection when once they are developed. The following description by John Ryan, in a commentary on dysentery, dated London, 1767, is perhaps as concise as any that can be given of the disease. He says: "A person afflicted with the more acute gripings in the belly, with a frequent inclination to stool, and who emits the evacuations with bloody or mucous matter is agreed to be troubled with a dysentery." We now use the word "tormina" to express the griping pain, which is sometimes excruciating, and "tenesmus" as "a comprehensive term for the morbid sensations referred to the anus and its vicinity, which consists in a feeling of fulness and weight with frequent constant inclination to go to stool and straining during the act of defecation, little or nothing being passed, and often of the nature of slimy mucus or blood, whilst no sense of relief is experienced afterwards."[1]

The disease as it comes under the notice of medical men for treatment is most naturally divided into two main classes of cases—namely, acute and chronic. "Acute" is used to express the first attack and before ulceration has been well established. "Chronic" is applied to any case the subject of which has at some previous period had one or more attacks and in which the ulcerative process is established. An attack may be associated with more or less fever. In many cases the fever is slight at the outset and disappears with the progress of the disease; in others it is high and persistent, belonging either to the intermittent or the remittent type. The term "malarial dysentery" has been applied to the latter form of case, but this, in my opinion, is a confusion, the symptoms being no doubt due to two distinct poisons, which must be treated independently of each other, so that the term "fever and dysentery" would be more correct. Vomiting is a symptom which in some epidemics is very prominent and is occasionally very intractable, more especially in women. In these cases it is probably due to reflex irritation to neighbouring nerve structures caused by the inflammatory process going on around the dysenteric ulcers. Another symptom which is very rarely seen is retention of urine due to spasmodic contraction of the urethra caused by reflex irritation of a dysenteric ulcer in the rectum. This is sometimes associated with paralysis of the sphincter ani, apparently due to the same cause.

Treatment.—There seems to be a universal consensus of opinion that the drug for the treatment of acute dysentery is ipecacuanha in large doses. Since its re-introduction into India by Dr. Docker about 1856 the death-rate from acute attacks has been reduced from 11 per cent. to less than 5 per cent., according to Sir Joseph Fayrer's statistics published in his work on "Tropical Dysentery and Chronic Diarrhœa," 1881. The following is his method of treating an acute case. "The patient should remain in bed. If there be abdominal pain or tenderness hot fomentations must be applied. A dose of from twenty to thirty grains of ipecacuanha powder, according to age, strength, &c., should be given to an adult in water, and the patient should endeavour to resist vomiting as long as possible. The dose of ipecacuanha is generally repeated in four or six hours, a second or third time according to effects, and especially if the first dose has been speedily rejected, as it often is." It is now usual to precede the dose of ipecacuanha with ten or fifteen minims of liquor opii, or some other form of opium, to prevent the tendency to vomit. For the same reason the ipecacuanha powder is often enclosed in a cachet or put in pill form. This treatment has one important drawback to general practice in that it entails personal supervision by a trained attendant in order to see that instructions are carried out, patients having a natural repugnance to taking a drug likely to cause vomiting. When we come to consider chronic dysentery there appears to be a similar general agreement among the most experienced men that no form of treatment is up to the present very successful. W. J. Moore in his "Manual of the Diseases of India," says in chronic cases that rest and quiet with a milk diet are the chief factors in treatment. Many chronic cases are little benefited by medicine and resist all treatment. Ipecacuanha affords very temporary relief. Dr. Chevers in "Diseases of India" gives no statistics of cases, but appears to consider the sub-acute, usually termed "chronic," form as very generally fatal in adults in the long run, opium and ipecacuanha being the drugs on which he places most reliance. Sir Joseph Fayrer says the prognosis in the advanced stages is uncertain; in the chronic more doubtful still—the ipecacuanha is no longer useful. He records five cases of chronic dysentery with three deaths, and recommends ten-minim doses of turpentine three times a day. Dr. (now Sir) Joseph Ewart in his article on Dysentery in "Quain's Dictionary of Medicine," after giving various directions for the treatment of chronic cases, says: "But it will often happen that in spite of the most careful dietetic, hygienic, and therapeutic management no substantial progress towards the repair of the ulcers is made, and the patient eventually dies worn out from suffering and the asthenia consequent literally on inanition."

The following statistics, kindly supplied by Dr. A. Crombie, Surgeon-General in Charge of the Calcutta Hospital, also bear out the same facts, and are further interesting as giving

[1] Quain's Dictionary of Medicine.

Hosted by Google

a fairly correct estimate of the ordinary percentage of deaths from dysentery in the general run of practice, where both acute and chronic cases come under observation:—

TABLE I.—*Showing Number of Cases of Dysentery Treated in the Presidency General Hospital, Calcutta, for the past ten years, from 1885–94 inclusive.*

Years.	Treated.	Recovered.	Died.	Percentage of deaths.
1885...	162	147	15	9·2
1886...	111	103	88	7·2
1887...	116	110	6	5·1
1888...	84	72	12	14·3
1889...	104	97	7	6·7
1890...	73	67	6	8·2
1891...	94	92	2	2·1
1892...	45	41	4	8·8
1893...	54	51	3	5·5
1894...	94	87	7	7·4
Totals...	937	867	70	7·48

Remarks.—The treatment has been nowise invariably ipecacuanha. In a very large proportion of the cases no ipecacuanha except what is contained in Dover's powder was given. The average duration of the cases was within one week. The fatal cases were, with one or two exceptions, chronic cases. Acute dysentery in this part of India is not a fatal disease. They are mostly of the type known as catarrhal dysentery. There is in such cases probably little or no ulceration of the bowels.

Although dysentery is very prevalent in South Africa it has been very difficult to obtain any statistics which are of much value owing to the way in which they are published. I collected the records of twenty-three cases treated in the Bulawayo Hospital from July, 1894, to July, 1895. Of these five died, three being chronic cases and the other two acute. Large doses of ipecacuanha had been used in several of the cases. The average number of days the patients were under treatment was fifteen. The percentage of deaths was 21 8.

We may fairly gather from the foregoing statements that up to the present, although acute dysentery appears to be fairly tractable under favourable conditions, chronic dysentery, on the other hand, appears to resist all the resources of medicine. In what follows I am about to show, however, that there is a drug which is, I think, specific in its action on both the acute and chronic forms of the disease.

In March, 1889, having not long finished my career as a medical student at the Middlesex Hospital, London, I commenced practice near Johannesburg, and was struck by the unsatisfactory results obtained both by myself and others who had been longer in the country in the treatment of certain diseases, especially the various forms of dysentery. It became a question in my mind whether the contents of the Pharmacopœia represented anything like the whole of the remedies which lie hidden among the products of nature especially those of the organic kingdom. As far as medicinal plants are concerned South Africa is comparatively an unexplored country, and it seems but reasonable to suppose that it should contain not a few plants with unknown properties possibly of high value. Some of those who have practised medicine in South Africa must have come across cases, either personally or by hearsay, in which persons, not members of our profession, have successfully treated diseases which were apparently not amenable to Pharmacopœial remedies. Such an instance occurred to me in 1890. In that year I heard from a trustworthy witness of three cases of children suffering apparently from a form of very acute diarrhœa and vomiting—a form which generally means an acute attack of dysentery, which at that time was proving very fatal among the juvenile population of the Rand—who had been successfully treated with drugs obtained from the flora of the district. We must, of course, deduct a large percentage from the records of cures stated to have been effected by those outside the profession, but we cannot shut our eyes to the fact that there are drugs in South Africa known to the colonists the knowledge of which was probably originally derived from the Hottentots and Bushmen of the Cape Colony, which, in the hands of qualified men, would be of the greatest value. One of my chief objects in writing this paper is to show, by the results of over 100 consecutive cases, that such a drug does exist—a drug which I think I shall succeed in proving is a more powerful remedy than any which we at present possess in the treatment of the various forms of dysentery.

This drug first came under my notice in June, 1890, when a friend of mine, who had been suffering for two months from a severe attack of dysentery, and whose recovery was despaired of by his two medical attendants, was cured by the administration of a tincture prepared by a colonist from plants which he obtained from the Cape. The history of the case is briefly this. The patient, aged forty-eight years, had been treated by two members of the profession in Johannesburg for the greater part of two months, and though at times he improved the course of the disease was from bad to worse, till at length both medical men gave him up and felt it their duty to indicate the same to the patient's family. His wife, seeing the state of her husband, decided as a last resource that she would try the effect of the drug in question, which had been given to her in the form of a spirituous extract made with French brandy by a friend who had great faith in the remedy. The result was that after the second dose of about two ounces, given at an interval of four hours, the patient went quietly to sleep, and on awaking about eight hours afterwards found the dysenteric symptoms had disappeared and felt entirely a new man. He finished his medicine in two more doses, and from that time made a rapid and uninterrupted recovery, since which time he has never had any return of the old complaint, and up to 1895 to my knowledge he enjoyed perfect health.

After this case came under my notice I obtained a preparation of the drug made with brandy from a man who, however, would not divulge the secret as to what the plant was from which the tincture was made. I used his preparation in all suitable cases with invariably good results. From June to December, 1891, I had medical charge of the men employed in constructing the Vaal River section of the Netherlands Railway in the Transvaal, and during that period I had about seventy cases of dysentery in which I conclusively proved to my own mind the value of the drug in question. After finishing my medical contract with the railway authorities in the beginning of 1892 I made up my mind to get hold of the plant from which the drug was prepared. In this I had the greatest difficulty, as the owner of the secret resolutely refused to give me a fresh specimen of the plant except at a prohibitive price. However, I succeeded in obtaining from him a portion of a stalk and a few leaves which had been macerated in preparing his tincture. This specimen, such as it was, I showed to two friends well versed in the African flora, but they failed to identify the plant, not having sufficient data to go upon from the absence of flower or seed-pod. Having ascertained that the plant did grow in the surrounding country I determined to search for myself till I found a plant with similar stalk and leaves. After six weeks' patient endeavour I was fortunate enough to discover what I felt sure was a young specimen of the same plant in the Potchefstroom district. This plant had no flowers or seed-pod, but on showing it to my friend, Mr. C. D. Appelgren, he recognised it as a specimen of Monsonia ovata, and at once pointed out flowering specimens of the plant growing within a hundred yards of his residence on the Vaal River. He kindly collected a good quantity of the plants for me, and from these I made a tincture by maceration in spirit in the ordinary way for British Pharmacopœial tinctures — viz., 2½ oz. to the pint of rectified spirit, which proved identical in its action to the one I had been using as supplied to me previously for the cases I had been treating. Since then, as will be seen from the records of cases, I have been using this drug in the treatment of dysentery, and afterwards in the Zoutpansberg district of the Transvaal collected other specimens, and again in Matabeleland, where I found the plant was growing on the Bembize River, about twenty-five miles from Bulawayo. A friend, Mr. Fynne, who was farming there kindly had a large quantity collected for me, with which I had hoped to continue my work on the drug; but, unfortunately, the Matabele rising took place, and the stock that he had collected had to be left behind in his flight for Bulawayo in March, 1896.

The plant is an annual and must be gathered in January or February, and as I had to leave for England in July with my wife and family any further work has had to be put off to a more convenient season. I have, however, a quantity of seed which I hope to succeed in raising in England this summer, and shall then be able to continue work, as I am convinced the plant contains properties which will prove

Hosted by Google

valuable for other forms of ulceration of the digestive tract besides dysenteric, but have not sufficient evidence at present at my disposal to justify me in making any statement.

I will now proceed to give the history of the cases treated, numbering 100, in which monsonia has been the remedy employed. Its action was sometimes supplemented with that of other drugs, as I found by experience that some specimens were distinctly more active than others, and situated as I was, with the necessity always of attending to my medical practice as a means of livelihood, it was sometimes very difficult to collect specimens which were really in proper order, and I was consequently obliged to use plants which were apparently too old and had certainly lost to some extent their medicinal properties.

CASE 1. *Chronic dysentery.*—The patient was a man aged thirty years. He was dark and well-nourished. He had had two attacks previously similar to the present one—the first in Aug., 1889, which lasted five days and for which he took a mixture, the composition of which he did not know, and was cured; and the second attack in May, 1890, which lasted ten days, and was cured by taking chlorodyne in doses of twenty minims every four hours. This, the third, attack began on Aug. 20th, 1890. He had been suffering from cold in the head for seven days previously. On the night of the 20th he felt very feverish, with occasional sensations of chill down the spine. There were pains all over the body, especially at the lower part of the spine. The bowels acted once during the day. On the 21st, at 7 A.M., he took two aperient pills, and at 10 A.M. the bowels were freely opened. He felt great pain in the left iliac region and lower part of

TABLE II.—RECORD OF 100 CONSECUTIVE CASES.

No.	Sex and age.	Nature of disease.	Date of commencement of treatment.	Date of convalescence.	No. of days under treatment.*	Remarks.†

the back. At 1 P.M. he commenced passing slime mixed with blood, and from then till midnight he had six dysenteric motions. On the 22nd he had four dysenteric motions up to 2 P.M., when he took fifteen minims of chlorodyne, and repeated the dose at 5 P.M., with the result that he had no return of the symptoms. On the 23rd I saw the patient about midday for the first time. The temperature was 100° F. and the pulse 75. The tongue was coated with white fur in the centre, but was clean at the edges and moist. The pain in the lower part of the abdomen had recommenced, and the patient frequently passed viscid mucus streaked with blood. Two doses of four drachms each of tincture of monsonia were given at intervals of four hours. The symptoms disappeared and the patient enjoyed good health for six months, after which period I lost sight of him.

CASE 2. *Acute dysentery.*—On March 4th, 1891, this patient, a man aged thirty years, swam the Klip River when in a very heated condition from previous exertion. On the 6th he felt feverish, with aching pains all over the body. The bowels became very loose and were open fifteen times during the day. The motions were feculent and mixed with mucus. On the 7th he commenced to pass mucus mixed with blood, with great griping pains and tenesmus. The bowels were opened twenty-five times. He took some powders prescribed by one of the medical men without effect. On the 8th I was summoned to attend the patient at Johannesburg and ordered him one drachm of tincture of monsonia every three hours. After the third dose the pain and tenesmus disappeared and the motions became feculent. He continued taking the drug during the daytime till the 12th, when the bowels became normal and only open once a day.

CASE 3. *Chronic dysentery.*—In May, 1890, a man, aged twenty-seven years, was suddenly attacked, while marching with a detachment of police in Bechuanaland, with pain in the lower part of the abdomen, especially in the right iliac region. Ten minutes later he passed a motion mixed with a large quantity of blood. Two days afterwards he was taken to Macloutsie Hospital, where he had from twelve to twenty dysenteric motions a day. He was seventy days in hospital undergoing various forms of treatment and was eventually apparently cured by doses (20 grains) of pulvis ipecacuanhæ. He returned to Kimberley by waggon and had another attack of dysentery on the road. On Aug. 2nd he went into the Kimberley Hospital for treatment and remained there till Sept. 8th, when he left for Natal. In March, 1891, he returned to Johannesburg apparently well. On the 13th, however, dull pain recommenced in the lower part of the abdomen and the bowels became loose. On the 23rd he went into Johannesburg Hospital suffering from a sharp relapse of dysentery. He was treated with large doses of ipecacuanha and left convalescent on the 26th. He continued on a milk diet, but the bowels again became loose, blood and mucus again appearing. On March 30th, 1891, I first saw the patient and ordered him one-drachm doses of tincture of monsonia every six hours. He passed a little blood occasionally till April 2nd. From that date till the 12th the dysenteric symptoms disappeared and the bowels gradually resumed their normal condition. For twelve months subsequently the patient enjoyed good health, after which I lost sight of him.

CASE 4. *Acute dysentery.*—A man, aged twenty-six years, was on July 20th, 1891, seized with a sudden attack of diarrhœa, accompanied by a burning sensation down the spine, with griping pains in the lower part of the abdomen. The temperature was 99° F. and the pulse 92. A lead and opium pill (5 grains) was administered, followed by a solution of quinine (5 grains) in dilute hydrochloric acid (5 minims) given every six hours in about a wineglassful of water. The pains disappeared and the patient felt better. On the 22nd he went to Johannesburg and stayed there till the 27th. During this time he was troubled with diarrhœa. On the 28th he returned to his work on the Vaal River Railway and in the evening passed some mucus and blood. During the 29th and 30th he took several doses of chlorodyne on his own account, but the dysenteric symptoms grew gradually worse. On the 31st at 8 P.M. I was called in to see the patient, who was then very prostrate and had been passing mucus and blood almost every half-hour for the last twelve hours with great pain and tenesmus. The pulse was 125 and the temperature 98·8°. I administered an enema of about a quart of warm water lightly coloured with permanganate of potassium through an irrigation tube and prescribed two-drachm doses of tincture of monsonia every four hours. The patient felt much eased, and went to sleep at 10 P.M. On Aug. 1st the patient awoke at 8 A.M. He felt much stronger. The pulse was 80. The bowels were opened twice during the day—feculent, with a little blood. The pain and tenesmus were almost gone. He was put upon a milk diet and the medicine continued. On the 2nd the bowels were opened once—semi-solid with a little streak of blood. On the 3rd a normal motion was passed. The patient was feeling well and walking about. He commenced ordinary diet. He remained in good health for six months, when he was last under observation.

CASE 5. *Acute dysentery.*—The patient was a man aged twenty-six years. On Aug. 4th, 1891, he sent for medicine for an acute attack of dysentery. He took four two-drachm doses of tincture of monsonia at intervals of four hours. When seen a week afterwards he said he was completely cured.

CASE 6. *Fever and acute dysentery.*—The patient was a woman aged sixty years. She was a stout person acting as nurse, and had been suffering for about four days from an attack of malarial fever with diarrhœa. She had pain all over the body, anorexia, feverishness, especially at night, and vomiting occasionally. When I called in to see her, on March 26th, 1891, she was in bed complaining of frequent vomiting, with severe general headache and frequent passage of mucus mixed with blood, with tenesmus and griping pains in the abdomen. The temperature was 103·6° F. and the pulse 84. A mixture composed of two drachms of liquor bismuthi, one minim of acidum hydrocyanicum dilutum, and ten minims of liquor morphiæ hydrochloratis was administered, together with a little weak brandy and water. This eased the pain somewhat and the vomiting ceased. About a quarter of an hour afterwards a dose composed of five grains of quiniæ sulphas, six minims of acidum hydrochloricum dilutum, in two ounces of water, was administered and was repeated every six hours. Half an hour after the quinine mixture had been administered two-drachm doses of tincture of monsonia were administered every four hours if the patient were awake. I saw the patient again on the 28th, two days after my first visit, when the dysenteric symptoms had entirely disappeared, but she had still some slight remains of the malarial fever. The temperature was 100°. The quinine mixture was continued and the patient went to Johannesburg for two days' change and completely recovered.

CASE 7. *Acute dysentery.*—The patient was a man aged thirty-two years. The temperature was 101 4° F. and the pulse 97. The bowels were moved twelve times during the last twenty-four hours. The motions were feculent, mixed with blood and mucus. There was pain in the limbs and lower portion of the abdomen and back. Tenesmus was not strongly marked. A mixture containing five grains of quinine was given three times a day and two drachms of tincture of monsonia every four hours. The next day, Nov. 16th, 1891, the bowels were normal, the temperature was 98 6°, and the pulse 70.

CASE 8. *Acute dysentery and drink.*—The patient was a man aged forty-two years. He had been drinking heavily for some three weeks. When seen on Dec. 16th, 1891, he was in a weak condition, passing blood and mucus every half hour. There was great tenesmus and pain in the abdomen. The patient stated that on the 14th he slept in wet blankets and the next morning was seized with great pain in the stomach accompanied by violent diarrhœa, which quickly took a dysenteric form. I gave him at once four drachms of tincture of monsonia followed by two-drachm doses every four hours. On Dec. 17th I saw the patient, who said that the dysentery had quite stopped and he was celebrating his convalescence in a rather convivial manner.

CASES 9 to 74. *Acute dysentery.*—These were cases of dysentery occurring among the Kaffirs working on the Vaal River Section of the railway from June to December, 1891. Forty-four of the total sixty-six cases occurred in the months of October and November and were mostly of an acute form. The treatment consisted in administering half-ounce doses of tincture of monsonia every four hours. In all except two cases only four doses were required. The Kaffirs were generally fit to resume their work on the second day after the first dose of medicine. The only exceptions were the two cases before mentioned, and in both of these treatment was continued for nearly a week before they were completely cured. After the first four doses, which were given at intervals of four hours, the motions became feculent with now and then traces of blood and mucus, and the treatment

Hosted by Google

was continued with two-drachm doses given three times a day.

CASE 75. *Acute dysentery.*—The patient was a young woman aged eighteen years. On May 28th, 1892, she complained of continual straining of stool, passing blood and slime. Two-drachm doses of tincture of monsonia were administered every four hours. I saw the patient again on May 30th, when she was convalescent and said that she began to improve after the first dose and had a refreshing sleep after the second.

CASE 76. *Acute dysentery.*—The patient was a man aged thirty-four years. When seen on Sept. 11th, 1892, his temperature was 101·2° F. The tongue was white with fur at the back; the pulse was 90. He complained of frequent tenesmus, passing very little slime and blood. An acid solution of quinine, containing four grains of the sulphate, was ordered three times a day and two drachms of tincture of monsonia every four hours. After the third dose the blood and mucus disappeared from the motion, which became feculent. On the 12th a powder consisting of eight grains of pulvus ipecacuanhæ compositus and ten grains of pulvis catechu compositus was administered with a drachm of tincture of monsonia, and all the unfavourable symptoms disappeared, and the patient has to my knowledge remained entirely free from dysentery up to the early part of 1896.

CASE 77. *Dysentery and fever.*—The patient was a man, aged thirty-six years, who was seen on Nov. 22nd, 1892. He had malarial fever in 1891 in Madagascar and had frequent relapses. On Nov. 22nd he had a sudden rise of temperature to 105° F.; the tongue was thickly furred and he had distinct symptoms of bilious fever. On treatment the temperature fell to normal, but acute dysentery intervened. Three doses of half an ounce of tincture of monsonia with ten drops of tincture of cardamom were administered at intervals of every four hours. On Nov. 23rd the patient had a fairly good night and felt much better. The motions were feculent, but a little tenesmus still remained. The patient was still very bilious looking. A powder containing four grains of calomel and ten grains of pulvis ipecacuanhæ compositus was given with a dose of tincture of monsonia. The symptoms disappeared, but during the night the patient felt an uncomfortable fulness. An emetic was given, and on the morning of the 24th the patient felt well enough to leave for the low country.

CASE 78. *Dysentery and drink.*—The patient was a man aged thirty-six years. When seen on Nov. 27th, 1892, he was suffering from general debility due to alcohol. At 1 P.M. symptoms of acute dysentery showed themselves, and during the afternoon he had several dysenteric motions. At 6 P.M. his temperature was 98·2° and the pulse 70. A powder containing fifteen grains of pulvis catechu compositus and six grains of pulvis ipecacuanhæ compositus, with half an ounce of tincture of monsonia, was administered, and on the 28th, when I next saw him, the dysenteric symptoms had disappeared. This patient died about a month afterwards from the effects of drink and possibly a return of the dysentery, but as he did not come under medical treatment I cannot say for certain.

CASE 79. *Acute dysentery.*—The patient was a man aged twenty-seven years. When seen on May 12th, 1893, he was suffering from bilious fever and acute dysentery. The dysentery was treated with two drachms of tincture of monsonia, ten minims of tincture of opium, and thirty minims of tincture of catechu every six hours. On May 15th the patient was convalescent.

(To be concluded.)

BEDFORD MEDICAL SOCIETY.—The annual meeting of this society was held at Bedford on Jan. 28th. The following officers were elected for the ensuing year:—President: Mr. R. H. Kinsey. Treasurer: Mr. A. Chillingworth. Secretary: Mr. W. Gifford Nash. After the meeting the members and their friends dined together. During the evening it was decided to send the congratulations of the society to Lord Lister on his elevation to the Peerage.

MEDICO-PSYCHOLOGICAL ASSOCIATION. — The spring meeting of the South-Western Division is to be held in the afternoon of April 27th at Barnwood House, Gloucester. After the transaction of business and the election of members Dr. Soutar will open a discussion on Recoveries in Asylums, and this will be followed by an important contribution from Dr. Goodall on the Systematic Collection of Patholog cal Data in Asylums.

MASTOID SUPPURATION FOLLOWED BY LATERAL SINUS PYÆMIA, TREATED BY PARTIAL EXCISION OF THE SINUS AND LIGATURE OF THE INTERNAL JUGULAR VEIN IN THE NECK.[1]

BY A. W. MAYO ROBSON, F.R.C.S. ENG.,
SENIOR SURGEON TO THE GENERAL INFIRMARY AT LEEDS; CONSULTING SURGEON TO THE BATLEY HOSPITAL;
WITH
HERBERT KEIGHLEY, M.R.C.S. ENG.,
SURGEON TO THE BATLEY HOSPITAL.

A MAN, aged thirty-seven years, was admitted to the Batley Hospital, under the care of Mr. H. Keighley, on Nov. 2nd, 1895, complaining of pain accompanied by a foul discharge from his right ear. The family history was good in all respects. The patient, a powerful and healthy man, never remembered having had any ailment apart from a periodic "discharge of matter" from his right ear. This had existed, he was told, from childhood, although he could not say whether it was subsequent to measles, scarlet fever, or other disease of infancy likely to give rise to such a condition. The discharge from the ear occurred two or three times a year and was always preceded by severe headache and pain in the ear. These attacks never lasted long nor did they compel him to give up work, and he used to make a boast to his wife that he always got well without the aid of a medical man, although she had frequently urged him to consult one. The present attack, which was more prolonged than any of the previous ones, and which led up to the operation, commenced in July, 1895. The patient had his usual premonitory symptoms of languor and headache, but the pain was not so severe as on former occasions and only occurred at night. At this time the discharge, which the patient described as "yellow matter," was mixed with blood. He did not leave off work. The ear discharged almost continuously till Oct. 27th, when it suddenly dried up. Three days later (Oct. 30th, 1895) the patient while at work was seized suddenly with a very severe pain extending all over the right side of his head and with a tendency to shivering. He, however, continued working the remainder of the day, but was compelled to remain in bed the following day. On Nov. 1st he was seen by Mr. H. Keighley, who found him suffering great pain in his right ear. There was no discharge from the ear, but the temperature was 102° F. and the pulse 96, the respirations being normal. He was removed to the Batley Hospital. Two days afterwards the patient's condition was much the same, but on the following day the tympanic membrane was seen to be inflamed and bulging, and on being punctured by Mr. Keighley great relief was afforded. The pus which escaped was very fœtid. Within twenty-four hours the patient had a most severe rigor in the early morning, followed by a temperature of 105°, pulse 130, and respiration 22; this was followed by a second rigor in six hours and by a third rigor in three hours. In the evening I was asked to see the patient in consultation with the staff of the Batley Hospital, who asked me to operate. I made an incision about two inches long behind the ear, over the right mastoid process. After trephining through hard and dense bone, which could only be perforated by the chisel and mallet, a quantity of very fœtid pus escaped; the cavity was well washed out, iodoform applied, and free drainage adopted. The lateral sinus was freely exposed and was bathed in pus, but as the blood was fluid in it the sinus was not interfered with. Directly after the operation and for the next ten days the temperature was quite normal and the patient seemed to be progressing satisfactorily. On the eleventh day he again had a severe rigor and a temperature of 105°, when I was again asked to see him. We decided on a further exploratory operation. By chipping away the bone with a chisel and mallet I freely enlarged the former cavity, when the lateral sinus was found to be black and filled with septic clot; this sinus I freely laid open, and as the walls were septic I removed as much of it as possible and

[1] A paper delivered before the Leeds and West Riding Medico-Chirurgical Society on Jan. 15th, 1897.

Hosted by Google

thoroughly washed it up to the torcular herophili until blood flowed freely from the distal end of the sinus, which I then plugged with gauze. As I could not clear the lower end so satisfactorily, in order to prevent septic clot being carried into the system I cut down on the internal jugular vein in the neck and ligatured it in two places at an interval of half an inch. After this operation the patient was very comfortable, being quite free from headache and pain. There was no return of the rigors, although the temperature for the next ten days ranged from 96° to 105°, when a quantity of pus escaped from the wound. From this time the temperature remained normal and the patient made an uneventful and complete recovery. The patient is now in good health and well in every respect. For the notes of this case I am indebted to Mr. H. Keighley, who also undertook the entire after management.

The case illustrates the danger of allowing chronic ear-suppuration to go untreated, but it is chiefly of importance because of the radical treatment adopted, not only in clearing out septic clot, but in removing as much as possible of the septic wall of the sinus, and in ligaturing the internal jugular vein in order to prevent particles of septic clot being carried into the circulation and providing fresh foci for blood poisoning.

Leeds.

CATALEPTOID REFLEXES IN THE MONKEY.[1]

BY C. S. SHERRINGTON, M.A., M.D. CANTAB., F.R.S.,
HOLT PROFESSOR OF PHYSIOLOGY, UNIVERSITY COLLEGE, LIVERPOOL.

A PHENOMENON came under my observation in the course of experiments upon monkeys at the commencement of the present year which seems sufficiently interesting to merit record here. Its occurrence, so long as certain conditions of experiment are maintained, appears regular and predictable. Although the character of the movements executed by the skeletal muscles when excited reflexly through the medium of the isolated spinal cord is variable, one feature common to them is their comparative brevity of duration. Many of them are, as pointed out by Fick and by Wundt years ago, hardly distinguishable in several particulars from the simple twitches elicitable from an excised muscle, so brief and local and incoördinate do they appear to be. Others are more prolonged and, as I have described in a paper recently communicated to the society, exhibit various forms of sequence or "march" (Hughlings Jackson). Without recapitulating the conclusions there drawn from the data given in that paper, I wish here to merely point out that of movements due to purely spinal reflex action, although some are fairly extensive, most are quite short-lasting, and not so prolonged as the longer of those that can be elicited under appropriate conditions from the cortex cerebri; also that if prolonged they, like the final phase of prolonged movements initiated from the cortex, often become clonic or exhibit that kind of action which in the paper referred to above I have designated "alternating."

The reflex movements, the subject proper of this note, are, on the contrary, of extremely prolonged duration, and absolutely devoid of clonic character and of alternating character. If the cerebral hemispheres be carefully removed—e.g., from a monkey—with avoidance of hæmorrhage and of fall of body temperature, and if sufficient time be allowed to elapse for subsidence in the animal of what may be called shock, movements can be evoked remarkably different from those I have ever seen elicitable as purely spinal or as cerebral reactions. If a finger of one of the monkey's hands be stimulated, for instance, by dipping it into a cup of hot water, there results an extensive reflex reaction involving movement of the whole upper limb. The wrist is extended, the elbow flexed, the shoulder protracted, the upper arm being drawn forward and somewhat across the chest. The movement occurs after a variable and usually prolonged period of latent excitation. The movement, although it may be fairly rapid, strikes the observer each time as perfectly deliberate; it is of curiously steady and "smooth" performance. Sometimes it is carried out quite slowly, and then, as a rule, the extent of it is less ample. The most striking feature of the reflex is, however, that when the actual movement has been accomplished the contraction of the muscles employed in it does not cease or become superseded by the action of another group, but is continued even for ten and twenty minutes at a time. The new attitude assumed by the limb is maintained, and that, too, without clonus or even tremor. In the instance cited—namely, that of the fore limb—the posture assumed suggests the taking of a forward step in quadrapedal progression, and in that posture the animal will remain for a quarter of an hour at a time. The degree of, for instance, flexion assumed in the new posture seems much dependent on the intensity and duration of the stimulus applied. If the degree is extreme the attitude of the limb may not be maintained to its full extent for the time mentioned; thus the elbow, at first fully flexed, will in the course of a minute or so be found to have opened somewhat. This opening can be often seen to occur *per saltum*, as it were, but the steps are quite small and recurrent at unequal intervals of between perhaps a quarter of a minute and a minute. After some relaxation from the extreme phase of the posture has taken place the less pronounced attitude—e.g., semiflexion at the elbow—may persist without alteration obvious to inspection for ten minutes or more. Apart from the occasional step-like relaxations the contraction of the muscles is so steady as to give an even line when registered by the myograph. A renewed stimulation of the finger excites further flexion, which is maintained as before in the way above described. The posture can be set aside without difficulty by taking hold of the limb and unbending it; the resistance felt in the process of so doing is slight; the posture thus broken down is not re-assumed when the limb is then released.

Analogous results are obtainable on the hind limb. Hot water applied to a toe evokes always, so far as I have seen, flexion of ankle and knee; usually of hip also. This movement is "deliberately" executed and always institutes a maintained posture. If the finger (or toe) of both right and left limb be placed together in the hot water there results symmetrical reflex movement of both the right and the left fore limbs (or hind limbs), leading to assumption of a fairly symmetrical posture by the right and left limbs respectively, the posture being similar to, but duplicate of, that evoked in the one limb only on excitation of that limb. This may appear a self-evident sequel to the observation given earlier, but is not so when an observation immediately to be mentioned is taken into consideration.

Not the least interesting part of the reflexes under consideration is a remarkable glimpse which they allow into the scope of reflex inhibition as regards the coördinate of movements of the limbs. Although the posture taken up by the right fore limb consequent upon excitation of a finger is symmetrically duplicated by the left limb when both hands are simultaneously stimulated, the effect of excitation of the two hands does not lead to symmetrical posture if the excitation be not synchronous but successive. If, when the right arm has already assumed its posture in response to an excitation of the right hand, the left hand be stimulated, there results, while the left arm in obedience to the excitation is lifted and placed in the flexed posture, an immediate and, if the stimulus be at all more than slight, complete relaxation of the right arm. The right arm drops flaccid while the left is raised and maintained in the raised attitude. Similarly, excitation of the right foot breaks down the posture assumed by the right arm, and conversely, and even more easily, stimulation of the right hand breaks down a posture assumed by the right leg. Again, a nip of the right pinna causes relinquishment of a posture assumed by the right arm or by the right leg. If the right pinna is pinched when both arms are in this cataleptoid posture, complete inhibition can be readily exerted on the right arm, but usually only partial relinquishment can be induced in the left arm. To exert complete inhibition upon the posture of the left arm the pinna pinched must be that of the left side. Similarly the posture reflexly evoked by appropriate stimulation of either hind limb can be inhibited by excitation of either pinna or of either fore limb, but predominantly by pinna and fore limb of the same side as the limb to be inhibited. The inhibition of the hind limb is much more easily elicited from the opposite hind limb than from the opposite fore limb or opposite ear. I have never yet seen it obtained diagonally upon the fore limb from the opposite hind limb.

The movements obtained in the limbs by exciting the limbs

[1] Communication to the Royal Society, Dec. 29th, 1896.

themselves are only cited above as examples to illustrate the general characters of the condition. The details of the results will be given in a fuller paper dealing with the subject. I was prevented from inquiring thoroughly into the phenomenon when it was first met with; but in the course of the present summer and autumn the investigation has been systematically undertaken. I will conclude this preliminary note by adding that throughout the observations the animal's respiration remains apparently unaffected by the stimuli effective to produce the various reflexes and inhibitions such as above described. The respiration is tranquil, rather deep, regular, and often somewhat frequent. The animal in all my experiments has been completely blind, but a sharp conjunctival reflex exists. The knee jerks are elicitable but are not exaggerated. The tonus of the sphincters appears about normal. The pulse is full, regular, and fairly frequent. I have not at present succeeded in evoking the cataleptoid reflex by simply placing the limb in the desired posture.

In applying the term "cataleptoid" to these reflexes I do so because the reflexes recall, in some respects, strikingly certain phases of hypnotic condition—by some writers distinguished as cataleptic—and because the strict significance of the prefix implies a steady maintenance of possession subsequent to seizure and is, therefore, peculiarly applicable here, whether these reflexes be or be not allied to hypnotic catalepsy.

Liverpool.

ON MENTAL AND PHYSICAL FEEBLENESS WITH ANALYSIS OF CASES.

BY FRANCIS WARNER, M.D., F.R.C.P. LOND., F.R.C.S. ENG.,

PHYSICIAN AND LECTURER ON THERAPEUTICS AT THE LONDON HOSPITAL.

DURING 1896 I had the opportunity of examining and reporting on many cases brought under notice of the Charity Organisation Society as "feeble-minded," but will here only deal with the first hundred as they were presented. After examination they were classed as follows:—

	Males.	Females.
Exceptional cases, requiring special care on account of mental or physical infirmity ...	37	31
Not exceptional cases	24	8
Number of cases examined and reported on	61	39

The "exceptional cases" are classed as:—

Imbeciles, including one girl, aged twelve years, paraplegic with double cataract. Her sister aged ten years, who is included below among the "feeble-minded," was also paraplegic with double cataract. A brother, aged eight years, had similar defects, but with better brain-power than his sisters	4	6
Feeble-minded, or feebly gifted mentally—i.e., distinctly deficient in mental power, but not to such a degree as to justify certification as imbecile	28	18
(Of these "feeble-midded cases" 4 males and 1 female were also epileptic; 6 males and 2 females were deaf, or had naso-pharyngeal obstruction; 2 males were affected with hemiplegia; and 1 male and 1 female suffered from disease of the spine.)		
Epileptic, not included above	—	4
(Of the nine cases of epilepsy—4 males and 5 females—one of the girls was mute and another was a moral imbecile.)		
Mentally exceptional or *moral imbeciles* not included above	2	1
Crippled or *physically defective* not included above:—	—	—
Infantile paralysis	—	1
Chorea	1	1
Leg amputated	1	—
Dumb with naso-pharyngeal obstruction ...	1	—
(The total number of cases crippled or physically defective was 8 males and 5 females.)		
Total number of cases reported as exceptional and needing care	37	31

In describing these cases previously to classifying them and giving a diagnosis it is necessary to record the facts seen, and for this purpose it is convenient to proceed according to four main classes of defect. 1. Developmental defects in size, form, and proportion of parts of the body, principally observing the cranium, palate, external ear, and the features individually. In the report[1] of the committee on the mental and physical conditions of childhood, forty-two such defects are defined besides others less commonly seen. 2. Abnormal nerve-signs observed in the balance, action or reaction in movement and coördination of parts moving. Twenty such signs are defined in the report. 3. The nutrition and physical health of the body. 4. Mental dulness or defect as elicited by questions asked of the patient and his appreciation of common objects and power to perform simple mental processes.

Among the more commonly observed nerve-signs the following may be mentioned: general balance, slouching or listlessness, the head may be dropped in place of being held erect, the shoulders asymmetrical, and the feet unequally planted with the knees bent. In the forehead there may be horizontal creases from over-action of the frontal muscles, or vertical creases produced by the corrugators. Fulness under the eyes resulting from relaxation of the orbicularis oculi is common in conditions of fatigue, and grinning or over-smiling is common in brain defect. The eyes may wander and not fix well on an object moved; on the other hand, the head only may be moved in looking at things in place of moving the eyes. The face as a whole may be wanting in tone and expression. The hands when held out in front in a well-trained, active child are on a level with the shoulders, pronate, the arms being straight at the elbow, parallel with one another the width of the chest apart, the hand straight with the forearm, all parts and the digits held in the same plane. In place of this straight posture the wrist may droop with the metacarpus folded or adducted, the fingers being bent as in fatigue or paresis. In the nervous child and the patient convalescent from chorea the wrist droops while the digits are over-extended at the knuckle-joints and there may be finger twitchings. Imitation of finger movements performed by the observer may be slow, with inexact coördination as produced by sight; this is a useful test of weak coördinating power in one side of the brain. Slow and inexact response in movement and in speech is a very important indication of deficiency of brain power. "Extra-movements" may be seen accompanying coördinated action, such as protrusion of the tongue before answering a question, or the head may be bent, or one hand placed behind the back; such uniformly repeated actions are not uncommon. Statistical inquiry shows[2] that both defect in development of the body and abnormal nerve-signs, either alone or in combination with other classes of defect, are much associated with brain conditions leading to mental dulness. Also, that nerve-signs alone or in combination with other defects are more frequent and potent causes of mental dulness than defect in development alone or in combination for boys, and also for girls when unassociated with low nutrition or physical delicacy. Some cases present one class of defect only; of the feeble-minded cases two boys and six girls presented all the four classes of defect; as a rule, the more classes of defect present the worse is the prognosis. It is, however, noteworthy that the "moral imbeciles," the worst group of mental cases, may present no defect in body, being well built, with a general good motor action, active and attractive and intelligent in reply, so that a judgment of the case is only made on the results of observing action under varied environment and on facts communicated by those in charge of the child.

Of the feeble-minded cases the report shows:—

	Males.	Females.
Cases with developmental defect without nerve-signs	1	—
Cases of nerve-signs without developmental defect	5	7
Cases with developmental defect and nerve-signs	21	11
An epileptic, feeble-minded, moral imbecile ...	1	—
Total	28	18

To enable us to give satisfactory advice concerning these cases, which occur abundantly in all sections of society, it is necessary to make a clinical examination, which should, I think, include what we see in development of the body and disproportioning of its parts and the features, and, also, in signs of brain action apart from mental tests proper which

[1] Report on the Scientific Study of the Mental and Physical Conditions of Childhood, with particular reference to children of defective constitution, and with recommendations as to education and training. Based on the examination of 100,000 children. Published by the committee at the Parkes Museum, London, W.

[2] See the writer's article in the Journal of the Royal Statistical Society, March, 1896.

Hosted by Google

are mainly elicited by speech. A further reason for recording abnormal nerve-signs as distinct from the developmental signs is that the separate nerve-signs may to some extent be removed in detail by training, while the gradual removal of each defect in movement and balance indicates the improvement effected by training and shows the teacher certain points requiring daily attention. I have spoken of a clinical examination for the purpose of mental classification; beyond this, of course, a medical examination is needed on the ordinary points of health and freedom from disease. It may be well to draw attention to the frequency of deafness and naso-pharyngeal obstruction, defect of the eyes, skin, teeth, and glands, in cases of mental defect; conversely, I would draw attention to the frequency of mental defect in cases brought under treatment for the conditions just mentioned. It has been shown in the published report that all cases with any developmental defect are more delicate than others, their tissues fall into low nutrition under adverse environment (this fact is specially marked in the case of girls under all circumstances). I cannot but think that the boarding-out of such children under the Poor-law, as has been proposed, will lead to difficulties in the future. The diagnosis, classification, and management of children and adults with mental dulness and weakness is a subject that has recently attracted much public attention, while our State departments have recognised that provision for the care of such cases is necessary. The subject appears to call for due consideration from our profession, especially now that educational questions are so widely discussed and some educational bodies are seeking assistance from medical men.

After receiving evidence from the early part of the inquiry of the Committee on School Children, the Royal Commission on the Blind, &c., reported in 1889 "that with regard to 'feeble-minded' children they should be separated from ordinary scholars in public elementary schools in order that they may receive special instruction, and that the attention of school authorities be particularly directed towards this object." The London School Board has provided day classes of special instruction at twenty-four centres, where over 1000 children, dull, backward, or feebly gifted mentally, are taught; this is apart from the classes for the blind and dumb carried on under the Education Act of 1893. Clearly for such cases further industrial training is needed when they leave school at fourteen years of age.

The subject here dealt with is a large one and presents many aspects, especially in individual cases which must be dealt with according to circumstances. The census shows that 24 per cent. of the population are of school age, and the examination of 100,000 children seen in schools showed that about 1 per cent. are distinctly below the normal in mental or physical conditions, which may best be dealt with in early life and who are improvable under early and continuous training.

Prince of Wales-terrace, Kensington Palace, W.

THE TREATMENT OF EMPYEMA BY A VALVULAR TUBE.

BY W. MENZIES HUTTON, M.D., F.R.C.S. EDIN.

THE results obtainable by treating empyema by incision and drainage with an ordinary tube are often far from satisfactory. Many cases certainly heal up fairly well, but in a large number of cases healing, if obtained, is only after many weeks, and then we get considerable falling in of the chest wall and diminished expansion of the lung on that side. Cases are continually occurring in which Estlander's operation becomes necessary, and then even healing does not always follow. Nor are these unsatisfactory results to be wondered at seeing the usual methods of treatment are only to provide free exit of pus without attempting to aid in the expansion of the lung. In cases following pneumonia, influenza, and other acute affections good results are got by the ordinary methods of treatment. In these, however, even when healing has resulted in two or three weeks, I have found in a number of cases examined, even after months, that there remained an appreciable falling in of the chest wall with diminished expansion of the lung on the affected side. To understand how a valvular tube will enable the lung to expand we must have clearly before us the condition of affairs when there is an opening into the pleural sac. The lung is collapsed and the respiratory movements of the lung are reversed. With inspiration we have still further collapse of the lung by air rushing in at the opening into the pleural sac and by the expanding lung drawing air out of the collapsed one. With expiration, on the other hand, air is expelled from the healthy lung and distends the collapsed one. This is only slightly seen with ordinary expiration, but with forced expiratory acts, such as coughing, it is very evident. This can be proved by removing a portion of the chest wall in animals, and was demonstrated on the human subject in Germany, where it was necessary to remove a portion of the chest wall with a tumour. Here with each inspiration the collapsed lung was seen to diminish still further and with a cough the lung filled the pleural sac. In animals a hernia of the lung may even result from excessive expiratory acts. It is seen also just after opening an empyema: with inspiration the discharge lessens or even ceases, and with expiration it is violently expelled. Now if we introduce a tube with a valve attached we see that with expiratory acts air and discharge are expelled, but with inspiration the valve closes and no air gets back into the pleural sac, and the lung remains so far expanded and is ready to expand still more with each succeeding expiratory effort. In short, the lung keeps what it gains. I have tried several kinds of valves and apparatus and have now got one which works admirably. It consists of a large indiarubber tube with a rectangular rubber flange about 5 in. long and 4 in. broad. It is of sheet rubber about $\frac{1}{16}$ in. thick. The tube is just long enough to go through the chest wall. Into this tube is fitted a right-angled piece of glass tubing to which is attached a large-sized indiarubber drainage-tube about 6 in. long, and to this a duck-bill valve made of fine indiarubber is attached. This valve is encased by a glass tube which protects it from pressure. Between the flange of the indiarubber tube and the skin is inserted a piece of gutta-percha tissue somewhat larger than the flange. This sticks to the flange and to the skin and assists in preventing air getting in by the side of the flange. The opening in the chest wall should be made in the mid-axillary line at the level of the sixth rib, as this is the part to which the lung last expands. A dependent opening is not necessary and may be disadvantageous. When we are dealing with the pleural sac we have a piston arrangement by which the lung with expiratory efforts expels the discharge. I have tried the apparatus in cases where the opening had been made posteriorly or anteriorly, and what occurs is this—the lung comes out to the opening and blocks it, while a cavity remains at the lateral aspect of the chest. After the opening has been made the indiarubber tube is introduced, and the flange lies against the skin with the gutta-percha tissue between. Pads of wool are placed over the flange, which is fixed by a domette bandage to the chest. The large drainage-tube with the valve is slid over the bent glass tube and the valve end is carried round the chest to the front of the abdomen, where it is enveloped in wool to absorb the discharge, and this is retained in position by a binder. When the flange has been applied and the valve attached one can demonstrate the valve working. When the patient coughs air and discharge are expelled between the lips of the valve, and when inspiration occurs the lips of the valve are seen to close tightly. If now the lips are opened by inserting a probe between them air is heard to rush in, showing that more or less of a vacuum has been produced within the pleural sac. I would claim for this apparatus that it is simple and works admirably; that it hastens the expansion of the lung without causing any traction on the lung, as do syphon methods of drainage; and that it is safe and comfortable to the patient, who usually expresses himself easier after it is applied, as it enables him to breathe and cough much more easily. After even twenty-four hours the respirations are much reduced in frequency. The valvular tube has a further distinct advantage, in so far that it prevents air going into the pleural sac and so prevents sepsis, which frequently occurs in empyema. The discharge will be seen often after a day or two to become simply serous. There is also a great saving of dressing, as all the discharge escapes into the wool over the abdomen, and a nurse can easily change this. The flange does not require to be touched every day. Once every four days is usually sufficient for the wound itself to be looked to. For this purpose the tube is removed and, of course, air gets into the pleural

Hosted by Google

sac, but as soon as the apparatus is re-applied a few coughs again expand the lung. As the lung expands the parietal and visceral pleuræ become adherent and obliterate the cavity. In acute cases the expansion may be complete in two or three days; in more chronic cases it may take ten days or more. I have seen a lung expand after it had been collapsed for eight months. The method is suitable for all cases except those in which a communication with a bronchus exists. It is rather difficult to know when complete expansion and adhesion have taken place. This can usually be determined by introducing a probe and feeling the lung. I append short notes of three cases which show the results attainable by this method.

CASE 1.—The patient was a woman aged thirty-eight years. She had an empyema which was treated in the ordinary way and apparently healed. Three months later it was found again discharging and there was a cavity which would contain about four ounces of pus. Great relief followed the application of the valve tube, especially by easing the breathing. Expansion occurred in five days; there was no recurrence.

CASE 2.—The patient was a man, aged twenty-two years, suffering from phthisis and empyema. This was opened and drained in the usual way for about twelve days. Then there was no sign of closure of the cavity and the valve tube was tried. The day after the tube was applied the patient was tested as regards his breathing by a spirometer. Three days later he was again tested and had now increased his breathing capacity by ten cubic inches. The discharge had also ceased and the lung was found expanded and adherent all over except for about one inch below the wound. This I expected to close and removed the tube. Just before the valve tube was used the pulse averaged 110 and the respiration 24 per minute. The temperature was 100° F. at night. On the second day after the pulse was 96, the respiration 18, and the temperature 99°. In this case I took out the tube a little prematurely, as some small re-accumulation occurred. The small cavity soon healed and three months after the patient had gained 21 lb. in weight.

CASE 3.—The notes of this case were kindly sent to me by Dr. Simpson of Golspie. The patient, a young man, aged twenty-three years, tall, phthisical, came in January, 1895, with a history of pleurisy two years previously, for which he was tapped in the Edinburgh Royal Infirmary, and also received injections of tuberculin. His left chest was filled with fluid, the apex beat being nearly under the right nipple. Aspiration was done several times and about ninety ounces of pus removed. As re-accumulation rapidly took place Dr. Simpson opened into the pleural sac through the sixth interspace and inserted the valve tube on April 1st. On April 5th the discharge had entirely ceased, the tube was removed, and the wound healed in a few days. The patient made an uninterrupted recovery, and in July was able to assist in haymaking and did most of the harvest work on his father's croft. By Oct. 14th he had gained nearly 2 st. in weight and could climb a steep hill without inconvenience to his breathing.

Space forbids further examples, but I think these will show what results may be gained by this method of treatment. I believe that by it we can gain a more rapid and more complete return to the normal in acute cases; in chronic we can get the lung to expand and be useful instead of the patient being worn out by long-continued suppuration, ending often in death or requiring the subsequent performance of Estlander's operation, which, if it stops the suppuration, deprives the patient of the use of the lung. This becomes a mass of tissue of low vitality, and, I believe, forms a fit nidus for the tubercle bacillus. The tube or valve may get blocked, but I have never had any trouble from this. If it should occur the apparatus is easily cleaned. The apparatus is to be had from Messrs. Walters and Co., 69, Lambeth Palace-road, London; or Messrs. Young and Son, Forrest-road, Edinburgh.

Edinburgh.

CLEVEDON CONVALESCENT HOME.—From the annual report of this institution, just issued, it appears that the past year has been a record one, 335 patients having been admitted. The total number of admissions since November, 1881, is stated to be 4168. The receipts for the past year were £801 and the expenditure £790. The reserve fund account shows a balance in hand of £65.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF RESECTION OF THE RADIUS FOR SARCOMA.

BY E. H. DOUTY, M.B., B.C. CAMB.,
ASSISTANT SURGEON TO ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

THERE is so little deformity in this case and the hand is so useful that I have thought it worth while to draw attention to it, as it may guide others to choose resection of the bone rather than amputation in cases of slow-growing endosteal sarcoma. The woman has fair grasping power and finds her hand useful to her in her household duties. The illustrations show (A) the state of the limb before the operation and (B) at the present time. The tumour pulsated in places and there was a history of eighteen months' growth. It proved to be a myeloid sarcoma. The patient was a widow, aged forty-eight years, and her personal and family history are without significance. I made a long incision over the outer aspect of the bone and extending to the middle of the metacarpus. I found the cartilages of the

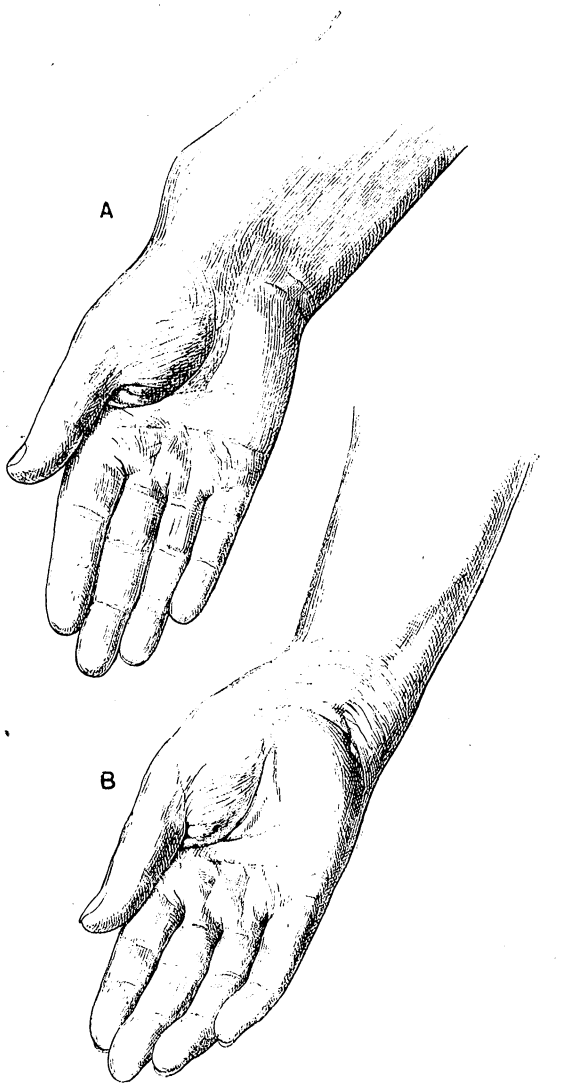

Fig. A. shows the appearance of the hand and wrist before, and Fig. B. after, the operation.

Hosted by Google

radio-scaphoid joint discoloured, and I therefore removed the scaphoid bone as well. The growth was strictly confined to the radius and to its lower end, not extending more than two inches up the shaft. It is now four months since th operation.

Cambridge.

AN AFFECTION OF THE FIRST PHALANGEAL JOINT OF THE HAND.

BY E. DONALDSON, B.A. T.C.D., L.R.C.S. IREL.

IT sometimes happens when the hand is closed and an attempt is made to open it that one of the fingers remains in a state of fixed flexion with the tip almost touching the palm. The fault lies in the first phalangeal joint. The patient has to use the other hand to raise the finger into the straight position. A slight snap in the joint mentioned may be felt at the time of extension. The finger after reduction can be flexed and extended freely. The trouble is apt to return. The joint does not swell and, with the exception of this liability to get "stuck," presents no apparent abnormality. This little ailment is somewhat annoying to the patient, though it is not painful. It appears to be rare. I have seen only one case. Mr. Jonathan Hutchinson has described three others.[1] I do not know if any one else has written on the subject. So far, the affection has been found either in the ring or middle finger, and it may be found on one side or on both. It may be recovered from. Up to this it has not been found in anyone under fifty years of age. In the case observed by myself, which is published in Mr. Hutchinson's "Archives of Surgery" (vol. vii.), the flexed and fixed condition of the ring finger was most likely to occur when a firm grasp of anything was taken. The patient could close and open the hand without any difficulty if she did not attempt to grasp anything firmly. This, although a trivial ailment, is a very interesting one. The joint affected is the first phalangeal, which has most to do with flexion of the finger. I think a subluxation of this joint occurs when the finger becomes fixed and flexed. The histories of the patients suggest that senile or rheumatic changes act as predisposing causes.

Londonderry.

A CASE OF WOOL-SORTERS' DISEASE.

BY ALBERT E. TUNSTALL, L.R.C.P., L.R.C.S. EDIN.

THE following case of wool-sorters' disease occurred recently at Denholme. The patient was a man, aged forty-two years, who had been engaged for several weeks sorting mohair at a factory where two men had died from wool-sorters' disease about eight months previously. He left his work at noon on Saturday, Jan. 2nd, 1897, apparently in his usual health. Upon rising from bed about 9 A.M. on the Sunday morning, having slept well through the night, he complained of headache, localising it in the centre of the forehead. This pain became worse, so that about 11 A.M. he went back to bed and remained there until 4 P.M., when he again rose and had a cup of tea, but could not eat. He returned to bed about 7 P.M., the pain being not less severe. He had a restless night, being quite unable to sleep. During Monday the headache eased a little, but he commenced to feel a difficulty in breathing and had a slight cough. He then vomited what appeared to be a large clot of blood very dark in colour. That night he again had no sleep. During the early part of Tuesday he seemed to be easier. I saw the patient for the first and only time about 5 P.M. on this day (Jan. 5th). He then complained of headache, but said it was not severe. He had had no sleep since Saturday night, and also had taken no food since then. The patient's chief complaint, however, was that he had difficulty in getting his breath, saying, "There is something here," at the same time striking his hand upon the front of the chest over the upper part of the sternum. He had a slight cough, with expectoration of clear, rather frothy phlegm. His breathing was not laboured. His face had a dusky hue, and a somewhat careworn expression. The patient anxiously inquired what his illness was, and whether I thought it was owing to his work. The temperature was then 100·4° F. and his pulse was 86 per minute. The heart sounds were normal, and examination of the lungs only revealed signs of slight congestion. He could converse freely and his case did not appear to be near its end. However, the difficulty of breathing increased and he expired rather suddenly and very quietly five minutes before midnight. The patient had been quite conscious and able to talk to his friends up to within five minutes of his death. I saw the body thirteen hours after death; the face, neck, chest, and arms were then of a black-red colour, the legs retaining their natural white colour. The face was also swollen. The body still felt warm and post-mortem rigidity had not set in. By the next day the colour had slightly faded in the face.

I am sorry that no post-mortem examination was made, as the friends of the deceased could not be prevailed on to give their consent and the coroner did not order one. The insidious onset of the illness and the absence of grave symptoms all through were most noticeable. The friends did not feel alarmed until the patient vomited on the Monday night, and then, owing to my living at a distance of three miles, they decided to wait until the next morning before sending for me.

Thornton, Yorks.

SEAMEN'S HOSPITAL, GREENWICH.

A CASE OF TETANUS TREATED WITH TIZZONI'S ANTITOXIN; RECOVERY.

(Under the care of Mr. G. R. TURNER.)

WE publish this week the notes of another case of tetanus treated with antitoxin, and our readers will recognise in it a type of the successful treatment of which more than one has recently been published—a young patient, a prolonged period of incubation, and slow development of symptoms. The case was by no means acute. The only example of the successful treatment of tetanus by the antitoxin serum which we were able to bring before our readers last year in the Mirror of Hospital Practice was a somewhat similar one.[1] It was the case of a boy, aged seventeen years, who had shot himself in the left hand. Stiffness of the jaw supervened on the twelfth day. Two days later antitoxin was given and the boy was convalescent in three weeks. The opinion of those watching this case as to the relative value of the serum and chloral hydrate is very striking. For the notes of this case we are indebted to Mr. E. Darbyshire, house surgeon.

On Aug. 31st, 1896, a boy, aged thirteen years, was admitted to the Seamen's Hospital, Greenwich, suffering from tetanus. The source of the infection was a wound inflicted by a rusty nail which the lad had trodden on about three weeks previously. At the time of admission there was a scar on the sole of the left foot with quite a healthy appearance, there being a scab over part of it, but no discharge. The patient first noticed his mouth feeling stiff and experienced some difficulty in opening it on the 26th, or about fourteen days after the injury. When the patient was brought to the hospital risus sardonicus was well marked and the teeth could not be separated more than a quarter of an inch. There was also slight stiffness of the neck. The parents had not noticed any "spasms." On the day after admission the back was stiff and the stiffness of the neck had increased. No convulsive movements of the limbs occurred. The boy was given ten grains of bromide of potassium and five grains of chloral hydrate every eight hours. On Sept. 2nd spasms of the arms were noticed, but these were not severe. At 9 P.M. on this date twenty grains of Tizzoni's serum were injected into the abdominal wall. No

[1] THE LANCET, Oct. 10th, 1896, p. 1012.

Hosted by Google

reaction made itself manifest either in the pulse, respiration, or temperature. The spasms were rather more frequent and certainly more severe during the night; the back was stiff and the abdominal muscles were firmly contracted, but no true opisthotonos was present. During the day of the 3rd the patient seemed better, the convulsions being very slight and infrequent, but at night they increased again in frequency and severity. On the morning of the 4th ten grains of serum were injected into the thigh under chloroform, after which the spasms were less. There was no effect on the pulse, respiration, or temperature. A third injection of ten grains was given late in the afternoon of the same day, after which the patient was quiet and slept well all night. He was now given ten grains of chloral hydrate every four hours. On the 5th there were a few slight spasms; the patient was very drowsy all day. The bowels were most obstinately confined, castor-oil, calomel, and enemas being tried from time to time, and all proving equally ineffectual. On the 6th the patient slept almost continuously all day; there were no spasms. The chloral hydrate was still administered every four hours. On this day there was retention of urine, and at midnight ten ounces were drawn off by catheter. The passage of the instrument caused a spasm. As the patient was very drowsy the chloral was discontinued at night, but the following morning the spasms were more frequent and severe. Chloroform was given and ten ounces of urine were withdrawn by catheter. An injection of ten grains of serum was administered and an olive-oil enema, which was retained for several hours and then returned without any fæcal matter. The patient was again quieter and in the evening passed fourteen ounces of urine naturally. The ten-grain doses of chloral were recommenced during this day (Sept. 7th) and were continued through the 8th and 9th, during which time the patient certainly improved and passed his urine naturally, though the bowels were still confined in spite of two more enemas. On the 10th the chloral was only given every eight hours and at night the spasms were again worse; and on the morning of the 11th the patient's mouth was more drawn and his eyes more nearly closed than they had been for three days. At 12.30 P.M. on this day another injection of ten grains of serum was given without any effect on the boy's condition, and at 6 P.M. his temperature was 100° F., the highest it had yet reached. The patient passed a quiet night, and on the 12th the bowels were slightly opened. From this date the patient steadily improved, no more serum was given and the chloral was gradually dropped. The bowels gave no further trouble, being freely opened each day quite naturally. During convalescence the boy was given a tonic of iron and nux vomica, and he was discharged cured on Oct. 6th.

Remarks by Mr. DARBYSHIRE.—The points of interest in the case are the long incubation period, the very healthy appearance of the scar, and the prolonged and obstinate constipation. To those watching the case the chloral hydrate seemed to have much more effect in controlling the spasms than did the serum.

SHEFFIELD GENERAL INFIRMARY.

A CASE OF PATHOLOGICAL RUPTURE OF THE BLADDER; OPERATION; RECOVERY.

(Under the care of Mr. ARCHIBALD CUFF, resident medical officer.)

RUPTURE of the bladder is comparatively so rare an event, from whatever cause it may arise, that this fact, together with the gravity of the accident, will invest the record of the following case with much interest. Rupture of the bladder may be either traumatic or due to some cause acting from within; in either case the rupture may be intra-peritoneal or extra-peritoneal. Cases such as the following are very rare and usually result from a combination of causes such as that mentioned by Mr. Cuff as probably present in the case under his care. In the majority of cases of idiopathic, or, more properly speaking, pathological, rupture distension of the bladder is a very important predisposing cause; whilst local weakness, the result of some process such as ulceration or new growth, is usually present. Mr. Rivington[1] writes that "in cases of stricture and retention," when the rupture follows over-distension and straining the aperture is usually a small perforation, or a short rent of about half an inch, or a triquetrous opening, or a round hole lined by mucous membrane. In cases of hypertrophy of the prostate the opening may be smooth and rounded or a narrow rupture with thinned or sloughy edges.

A man, aged forty-seven years, was admitted into the infirmary under the care of Mr. Charles Atkin (to whose courtesy Mr. Cuff is indebted for permission to publish these notes) on March 28th, 1896, complaining of intense pain in the abdomen, which, commencing a fortnight before admission, had been increasing in severity ever since. The following history bearing upon his condition was obtained partly at the time and partly subsequently. Fifteen years ago he had suffered from a smart attack of gonorrhœa, attended with the passage of a blood-stained discharge during its most acute stage and followed by a gleet which lasted six months. Since that time he had always had trouble in passing urine, his symptoms being those which usually attend a stricture of the urethra—namely, frequent and painful micturition. He was perpetually wishing to pass urine, especially, he said, when on a railway journey. The quantity of urine passed at any one time was small, varying from a "teaspoonful to a small cupful." During the act he had to strain, sometimes so much that tears would come into his eyes from the pain. Now and then there was dribbling of urine from the meatus, indicating an over-stretched urethra and sphincter behind the obstruction. For the last three years, dating from symptoms of what was probably a sub-acute cystitis, his troubles had been worse. There had been after this frequent attacks of pain in the loins and in the lower part of the abdomen and his urine on several occasions had been noticed to be turbid and of a bad odour. At Christmas, 1895, he had had one of the worst of these attacks, but they had all in time passed off, leaving him with only the irritability of the bladder to trouble him. A fortnight before admission, when in fair health, and free from pain, while endeavouring to raise a long and heavy ladder from a wall and having to strain considerably to effect this, he distinctly felt something "give way" in the lower part of the abdomen. This was accompanied by only slight discomfort, which lasted through the day. He did not remember whether at this time his bladder was full or empty. Urination was not accompanied with more pain than he had been accustomed to. But that night the discomfort deepened into pain, and this became so severe that on the next day he called in his medical attendant. In spite of all treatment he became worse, vomited several times, had shivering fits, and his temperature rose progressively. At the same time a tumour made its appearance in the hypogastrium. He was finally sent to the Infirmary. On admission his temperature was found to be 106° F. and he appeared to be extremely ill. Ten grains of sulphate of quinine were given and the temperature fell to 101·5°. But it soon rose again and he had a severe rigor. About 11.30 P.M. he had another rigor and his temperature was then 103·5°. It was while in this rigor that Mr. Cuff first saw him. His countenance was flushed to a rosy red, the eyes were suffused, and the skin was dry and burning to the touch. The jaws were so tightly clenched that Mr. Cuff could get no reply to any questions from him. So powerful were the muscular spasms that the bed was clattering on the floor and all the inmates of the ward were kept awake by the noise. The patient's pulse was 140, small, and "running." On examining the abdomen a firm, ill-defined mass was felt in the hypogastrium, extending upwards nearly to the umbilicus, and laterally to the level of the mid point of Poupart's ligament. An indefinite sense of fluctuation was to be made out. The abdominal walls were tense and not moving very much with respiration, but there was not any especial tenderness on pressure. This and the absence of vomiting seemed to exclude a general peritonitis. Neither did the swelling extend into the right iliac fossa in such a fashion as to make it likely that appendicitis was at the bottom of the mischief. The bladder was next turned to, and a catheter passed into the urethra, where it soon was engaged in a tight stricture. This being overcome the instrument was passed into the bladder, whence a small quantity of alkaline turbid urine was withdrawn. The abdominal swelling lay between the point of the catheter and the abdominal walls and hence in front of, and above, the bladder, and the working diagnosis of a suppurative peri-cystitis was made. Owing to the unavoidable absence of Mr. Atkin, Mr. Cuff was requested to do whatever was necessary, and decided to explore

[1] Heath: Dictionary of Practical Surgery, vol. i., p. 152.

Hosted by Google

the swelling there and then. Accordingly, at midnight, March 28th, chloroform was administered, and a sound passed with some difficulty into the bladder which felt as if it was embedded in plaster-of-Paris. Its cavity was small and contracted, and its walls hard and resisting. An incision two inches in length was made in the skin of the abdomen in the median line, immediately above the pubes and the interval between the recti was opened up. Continuing the incision Mr. Cuff next cut through what appeared to be a mass of thickened and inflamed connective tissue and finally opened up a cavity—or rather a series of cavities like the pores of a sponge—containing blood-stained urine on the surface of which a glistening scum was floating. This collection of connective tissue, which extended as far as could be made out over the front and sides of the bladder, was apparently the result of chronic inflammation and accounted for the feeling of thickening of the walls of the bladder, the distance between the point of the sound and the fingers being about three-quarters of an inch. One of the small cavities in this mass led down to the bladder wall and communicated by a small opening with its interior, the tip of the sound being felt through it by the fingers in the wound. So far, however, no collection of pus had been found to account for the condition of the patient, his temperature, &c.; and as the operator appeared to be cutting well below the superior limits of the swelling the incision was cautiously enlarged in an upward direction. Here a cavity was found containing about three ounces of a most foul-smelling pus. The wound was well syringed out and a flanged drainage-tube inserted into the cavities. The patient, who was somewhat collapsed, was put back to bed, and a catheter, connected with a piece of tubing dipping into a vessel of carbolic acid solution, was passed into the bladder and tied in to ensure proper drainage. The temperature fell almost immediately to 100°, and on recovering from the anæsthetic the patient expressed himself as feeling much better. Next morning the temperature had risen to 101·4°, but the general condition otherwise seemed to be good. The surface of the wound was discharging freely, and smelt of urine. The urine drawn off seemed to be clear. The temperature kept between 99° and 100° until April 3rd, when it fell to normal, but on the 8th (the twelfth day from admission) it rose again to 103°, and a sharp attack of facial erysipelas, starting from a small scratch on the nose, set in. Seven days later the temperature was again normal, and the patient has progressed favourably since. The abdominal wound has healed, but above the pubes there is still a small hard mass to be made out on palpation. A catheter has been passed regularly, and the patient says he is now passing urine with more comfort than he has known for years.

Remarks by Mr. CUFF.—It seems clear that here was a bladder the walls of which were probably pushed out into sacculi from the prolonged straining of micturition, consisting only of mucous membrane, and this softened and ulcerated from the effects of the recurring attacks of inflammation, from which the man suffered. Under the muscular strain put upon such a bladder by the abdominal muscles in lifting a heavy weight, one of these sacculi had given way and permitted of the escape of urine on to the anterior surface of the organ and, fortunately, outside the peritoneal cavity. That little was enabled to so escape—and the widespread areas of sloughing seen in traumatic cases were not present in this case—was due in all probability to the great inflammatory thickening serving to support and strengthen the walls of the bladder and opposing the spread of a fluid in its meshes. This thickening, the result of a long-continued chronic cystitis, finds an analogy in the thickening produced by a chronic urethritis extending through the mucous membrane of the urethra and involving the tissues of the corpus spongiosum. To the good influence of this thickening outside the bladder may be attributed also the absence of shock, it permitting only a very small breakage of the bladder-wall at first, this becoming larger subsequently by erosion from the escaping urine. It is interesting to note that the abscess present had not formed at the spot of rupture, but at a point nearer the peritoneal cavity, and hence nearer to the infecting intestines. The extravasated urine had set up an acute inflammation all around it, but only that portion of the exudation nearest the intestines had been invaded by pus-forming organisms. Pathological rupture of the bladder is one of the rarest forms of rupture to which that viscus is liable. It is due in some cases to the bursting of an ulcerated wall or sacculus; in other cases to the sloughing of the wall from pressure—e.g., by retroverted gravid uterus—or inflammation; the relative numerical proportion of cases of pathological rupture to cases due to traumatism is uncertain. Rivington, quoted by Henry Morris, collected seven cases of rupture associated with ulceration or sacculus, and nine due to pressure by a retroverted gravid uterus, out of a total of 322 cases of rupture from all causes. Of the 7 cases, 3 were intra-peritoneal, 3 extra-peritoneal, and 1 doubtful.

PAISLEY INFIRMARY.

A CASE OF SIMULTANEOUS DISLOCATION OF BOTH ENDS OF THE CLAVICLE WITH FRACTURE OF THE SCAPULA.

(Under the care of Dr. W. F. GIBB.)

THE small number of cases in which simultaneous dislocation of both ends of the clavicle has been met with makes the record of this one exceptionally interesting. It is evident that considerable violence was required to produce the displacement and it is very probable that it was applied in the only direction which renders this displacement possible. In spite of the shape of the joints at each end and the position of the bone, injuries to the shoulder far more frequently result in fracture of the clavicle or in dislocation of the humerus than in displacement of either end of the clavicle, for the ligaments which hold it in position are very strong.

A man, aged sixty-four years, was admitted to the Paisley Infirmary on May 19th, 1896. He had been coming down a plank gangway at a building in the course of construction, when he fell, alighting from a height of about four and a half feet on the point of his left shoulder. He was tall, bony, and about 11½ st. in weight. When seen by Mr. J. A. Graham, junior house surgeon, at 7.15 A.M. he was suffering pretty severely from shock, the accident having occurred at 6.30 A.M. The clavicle at its sternal end was dislocated downwards and forwards, forming a very prominent swelling at the top of the sternum. The rhomboid ligament was evidently torn through. The acromial end of the clavicle was displaced inwards about an inch and a half from its articulation with the acromion, so that the bone lay in an almost antero-posterior direction instead of its usual position; from the acromion inwards, forwards, and downwards. On taking hold of the two ends of the bone it could be lifted and moved backwards and forwards. There was a starred fracture of the infra-spinous fossa of the scapula and a suspicion of fracture of the ribs, though this last could not, on account of the swelling of the tissues around, be made out with certainty. There was considerable embarrassment of respiration from chronic bronchitis. Dr. Gibb confirmed the above diagnosis at his visit at 4 P.M. The patient was put to bed and supported by pillows in a semi-recumbent posture. The arm was placed in a dislocation sling and secured to the body by a bandage. The hand, however, slipped down and the bandage greatly impeded his respiration. The dislocation was not materially affected by the slipping of the hand, his posture appearing to benefit it more than anything. Accordingly, an ordinary sling was substituted and a binder lightly applied round the arm and chest. On May 27th he died from bronchitis. No post-mortem examination was obtainable.

Remarks by Dr. GIBB.—The above case is put on record on account of the rarity of simultaneous dislocation of both ends of the clavicle. In "Heath's Dictionary of Practical Surgery"[1] only four cases are mentioned as having been recorded. In "Ashurst's International Encyclopædia of Surgery"[2] it is stated that "a few cases of this rare form of luxation are said to have occurred." In "Treves's System of Surgery"[3] there occurs: "This accident is one of the curiosities of this part of surgical literature, and is generally produced by extreme violence. The sternal end is thrown forward, the acromial backwards."

PATHOLOGICAL SOCIETY OF LONDON.

Hæmorrhagic Diphtheria.—Ulcerative Endocarditis affecting a Malformed Aortic Valve.—Graves' Disease with Persistence of the Thymus Gland.—Exhibition of Card Specimens.

A MEETING of this society was held on Feb. 2nd, the President, Mr. H. T. BUTLIN, being in the chair.

Dr. J. W W. STEPHENS and Mr. C. D. PARFITT showed specimens from three cases of Hæmorrhagic Diphtheria. In all these cases purpura and hæmorrhages from the mucous membranes developed before death, which occurred from septicæmia and not from laryngeal obstruction. Cultivations were made after death from the heart's blood, lungs, spleen, kidneys, and other organs. In each case diphtheria bacilli were found in the cultivations from the lungs, confirming the previous observations of Kanthack and Stephens. In the heart's blood in one case diphtheria bacilli were found, in the second the pneumococcus only appeared in the culture, while in the third both diphtheria bacilli and streptococci were found in the blood. The diphtheria bacilli obtained on culture proved fatal to guinea-pigs, but the toxic effects could be with certainty avoided by mixing the culture with diphtheria antitoxin. By hæmorrhagic diphtheria they meant diphtheria accompanied by hæmorrhages under the skin and mucous membrane and not those where some hæmorrhage occurred at the seat of the disease.—Dr. A. A. KANTHACK said the cases illustrated the value of complete bacteriological investigation of every case as was actually carried out at the Johns Hopkins University. The ultimate cause of death in many non-bacterial diseases was due to the multiplication of pyogenic and other organisms in the blood. He did not believe that diphtheria was a purely local disease. The diphtheria bacillus could nearly always be obtained from the lungs.—In answer to Mr. KESTEVEN, Dr. STEPHENS stated the hæmorrhages were supposed to be due to the intensity of the septic infection and not to a pre-existing purpuric diathesis.

Dr. ARCHIBALD GARROD showed specimens from a case of Ulcerative Endocarditis secondary to Disease of the Middle Ear in a man aged thirty-nine years. The endocarditis affected the aortic valves, which exhibited a congenital malformation, there being only two large cusps of equal size. There were infarcts in the spleen and left kidney and in the lower lobe of the left lung which was the seat of pneumonic consolidation. Cultures from the pus from the left middle ear and from the heart's blood yielded abundant colonies of pneumococci and a few of streptococci, staphylococci, and the bacillus coli. Sections of the endocardial vegetations, stained by Weigert's method, showed numerous diplococci. The case was of interest, not only as an example of pneumococcal endocarditis, but also as illustrating the association of a congenital cardiac lesion with another congenital anomaly—viz., almost complete absence of the left lobe of the liver. The enlarged right lobe, which was cirrhotic, lay in a vertical direction. This case, taken in conjunction with another from which specimens were shown, suggested that congenital cardiac lesions, like acquired ones, may predispose to the attacks of bacteria upon the endocardium, for the malformed valves were in each instance alone attacked.—Dr. H. D. ROLLESTON referred to an exactly similar specimen of ulcerative endocarditis on a malformed aortic valve in the museum of St. George's Hospital. He suggested that two of the cusps might have become fused from endocarditis in very early fœtal life.—Mr. S. G. SHATTOCK did not think fœtal endocarditis had been the cause, as if so stenosis would have been present.—Mr. TARGETT had examined a liver showing a similar deficiency of the left lobe, and had searched without success for any arterial abnormality which might have caused it.—Dr. GARROD, in reply, said that in his specimen the two cusps were of equal size, and each had a single corpus Arantii. He thought one cusp had been suppressed.

Dr. HECTOR MACKENZIE and Mr. WALTER EDMUNDS read a paper illustrated by drawings and lantern slides on two cases of Graves's Disease with persistence of the Thymus Gland. This association was frequently met with by pathologists, but more experience was required before its constant presence could be affirmed, but it was too frequent to be accidental. It had been suggested that as the result of the disease the normal atrophy had been arrested or even that the remaining thymus tissue had hypertrophied. Administration of thymus gland had been recommended in this disease. Dr. Mackenzie had given it in twenty cases, but with negative results, except that there was some improvement in the general health. One of the cases brought forward in this communication had been so treated without benefit. The first case was that of a woman thirty-one years of age. Symptoms had been present for five years. At the end she emaciated rapidly and died from exhaustion. Each lobe of the thyroid gland was of the size of a hen's egg. The vessels on the surface were dilated. The thymus gland was persistent and spread out like an apron over the pericardium, being a quarter of an inch thick. The two lobes were nearly in contact in the middle line. The substance was pale. The second case was that of a woman who died at the age of thirty-five years, having suffered from the disease for one and a half years. The case was complicated with ascites and general œdema. The thyroid gland was much enlarged and uniformly so. The veins on the surface were greatly dilated, but the interior of the organ was not abnormally vascular. The two lobes of the thymus gland were present, but in an atrophic condition. The heart was much hypertrophied, although the valves were normal. There was chronic peri-hepatitis and there were signs of old pelvic inflammation. The thyroid glands and the thymus glands from the two cases were examined microscopically. The thyroid glands showed (1) the colloid so altered that it did not stain deeply with the usual re-agents; (2) the vesicles were enlarged and their shape altered—instead of being square, with rounded corners, they were oblong and branched; (3) the lining membrane was convoluted; and (4) the secreting cells were columnar instead of cubical. The thymus glands were not much altered, but degenerated and opaque concentric corpuscles were less common than in the normal organ, and in their place were enlarged corpuscles less degenerated and not opaque. One of the thymus glands contained eosinophilous cells, but this was not abnormal.—Dr. ROSE BRADFORD had examined four cases of Graves's disease post mortem; in all of them the thyroid gland was persistent and enlarged, in one case being thick and fleshy. He had seen the same condition present in some cases of leucocythæmia, Addison's disease, and lymphadenoma.—Dr. BERTRAM ABRAHAMS confirmed what had been said as to the inefficacy of thymus extract in Graves's disease, although it was of value in other forms of goitre.—Dr. MACKENZIE, in reply, said that he had found the thymus gland persistent in other cases, and showed one specimen from an elderly man who died from emphysema and a dilated heart. Its persistence in cases of Graves's disease appeared to be constant, but he should not like to hazard an opinion yet as to the significance of this fact.

The following card specimens were exhibited:—

Mr. D. DREW: Obturator Hernia.

Dr. CYRIL OGLE: (1) Ulcerative Colitis associated with Paraplegia; and (2) Hæmatoma of the Dura Mater.

Dr. B. HUNT: Myoma of Uterus weighing 34 lb.

Dr. F. LEWIS: Epithelioma of the Œsophagus and Scirrhus of the Pylorus in the same specimen.

Dr. HEBB: (1) Ulcerative Endocarditis in a Malformed Heart; and (2) Pendulous Tumour pressing on the Cervical Region of the Spinal Cord.

OPHTHALMOLOGICAL SOCIETY.

Spontaneous Recovery of a Retinal Detachment.—Retention Cyst of the Lacrymal Gland or "Dacryops."—Exhibition of Cases and Card Specimens.

AN ordinary meeting of this society was held on Jan. 28th, Mr. E. NETTLESHIP, President, being in the chair.

Dr. LAWFORD KNAGGS described a case of Spontaneous Recovery of a Retinal Detachment. A woman, aged twenty-one years, was shot in the right temple on May 21st, 1892. The bullet passed below the right orbit and lodged in the floor of the left antrum. The wound healed quickly. Attention was drawn to the right eye by the patient's complaints of inability to see things in certain portions of the field. Two choroidal ruptures near, and œdema around, the macula, and several large hæmorrhages were seen on the 22nd, and

Hosted by Google

from that date till the early part of July an acute attack of central choroiditis, with much effusion, was observed in its various stages. At the latter date a large mass of white lymph occupied the vicinity of the macula, and was surrounded by a broad frame of pigment, over which several vessels curled, to be buried beneath the mass of lymph. On July 27th a detachment of the retina had formed, which, when seen end-on, was of the shape of a wedge of cheese with its apex uppermost. The top of the detachment formed a ridge, which ran horizontally backwards till it merged in a track which disappeared beneath the inflammatory mass overlying the macula. The front of the detachment probably reached to the ora serrata. The field showed scotomata corresponding exactly to the central mass and the detachment. The patient was not seen again till Nov. 28th, 1893, when the detachment was found to have disappeared completely, and the re-applied retina to be quite normal in appearance. The central mass had become more triangular in shape, but the track which had led to the detachment was still visible. The scotoma caused by the detachment had gone, and that dependent on the central disturbance had slightly contracted. Central vision was destroyed. The condition was unchanged some time later. There could be no doubt that the detachment was produced by exudation gravitating after expression from the central mass of inflammatory tissue, or possibly from a concealed detachment behind it. A detachment produced by inflammatory serum, whose natural tendency was towards absorption, differed essentially from a detachment where the subjacent fluid was a passive effusion filling a potential vacuum. Detachments of the retina were divisible into three groups: (1) those occurring in fairly healthy eyes as a result of concussion in some form, as in coughing, blows, &c.; (2) those where it is the direct result of inflammatory effusion dependent on severe traumatism or on some organic disease; and (3) those met with in eyes which are the subjects of some chronic disease, such as myopia, where degenerative as well as inflammatory changes may share in the production. In Groups 1 and 2 spontaneous recovery was more probable and surgical treatment more hopeful (in suitable cases) than in Group 3. These statements were illustrated by references to recorded cases.—Mr. CANT supplied an account of another case in which absorption and cure occurred in a similar condition, resulting from a blow from a cricket-ball in a man aged twenty-four years. The eye, though myopic to the extent of 5D., was previously healthy. The detachment was treated by pad and pressure to the globe, the retina becoming re-attached, while vessels could be seen growing on its surface.—The PRESIDENT mentioned the case of a woman, aged thirty years, in whom detachment occurred spontaneously in both eyes which were previously myopic. Under pilocarpine recovery took place till the vision equalled $\frac{6}{18}$, but the detachment recurred three years later.

Mr. ARNOLD LAWSON read a paper on Retention Cyst of the Lacrymal Gland. The patient was a young married woman, aged nineteen years. The tumour had been growing for about four months when first seen. It caused a swelling in the upper and outer part of the left upper eyelid, and was accompanied by considerable ptosis, slight proptosis of the globe downwards and forwards, and slight limitation of movement upwards. On raising the upper lid a soft elastic tumour immediately bulged forwards between the lid and the globe. The tumour was obviously cystic, and had a dark bluish appearance. The skin moved freely over it. There were no glandular enlargement and no pain, and the general health was excellent. The tumour, which grew rapidly whilst under observation, was removed by dividing the external canthus, and having by this means everted the lid an incision through the fornix conjunctivæ completely exposed the anterior surface of the tumour. It was then shelled out without much difficulty. It lay perfectly free and non-adherent, except along its anterior surface, where it was attached by tags to the subconjunctival tissue of the lid, and at its outer margin, where it seemed to be adherent to the lacrymal gland. The cyst measured 40mm. in length, and 22mm. in breadth at its thickest part, and bore a remarkable resemblance in size and shape to a pigeon's egg. Its walls were of extreme delicacy and very translucent. It proved to be an unilocular cyst with a very shaggy inner wall, and contained about two drachms of a pale, straw-coloured, limpid fluid with a small sediment. Microscopically, the cyst wall was found to consist of a very delicate, loose, wavy, and elastic areolar tissue, denser and more felted toward the external wall. There was a remarkable absence of the cellular element, and it was only after repeated examinations of many sections that any cells could be found lining the cyst wall. Ultimately a few clusters of very minute cells with large nuclei were found scattered here and there in a few of the sections. The cells were of irregular shape and grouping, but strongly suggested a glandular origin. The cyst fluid was neutral, of a light specific gravity, and contained a fair amount of albumin and a distinct trace of chlorides. The chief feature of the fluid was the presence of numbers of homogeneous bodies presenting great variety of size and shape. They were almost transparent, but stained readily. There were also present large numbers of leucocytes and red corpuscles, both floating free and also adherent to the bodies and embedded in them. The presence of fibrin in these bodies was demonstrated by staining after Weigert's method, and they were considered to be probably small detached masses of an albuminous nature which had been coagulated, the precipitation of the albumin being brought about by the presence of alcohol, in a weak solution of which the cyst was lying for some days before examination, and the coagulation resulting from the formation of fibrin from the blood elements in the cyst. This theory was supported by the constant presence of adherent and embedded leucocytes in these bodies. As a further explanation a possible analogy was suggested between the bodies and hyaline casts, probably derived from some proteid of the renal epithelium, the urine in which they were found being nearly always albuminous. The presence of the epithelial lining to the cyst, the glandular type of the cells, the situation of the cyst, the presence of sodium chloride in the fluid, and the limpid character of the fluid itself point very strongly to its being a retention cyst of the lacrymal gland, a disease of extreme rarity. A parasitic origin was suggested for the cyst on account of the curious bodies in the fluid, but the nature of the cyst wall placed such a diagnosis out of the question.—Mr. DEVEREUX MARSHALL described some curious bodies in the fluid apparently of a hyaloid nature, with flattened epithelial cells.

The following cases and card specimens were shown:—

Dr. MACNAUGHTON JONES: Case of Congenital Closure of the Lacrymal Punctum and Absence of the Canaliculus.

Dr. WORK DODD: Peculiar Changes in the Fundus Oculi.

Mr. JULER: Changes in the Macula.

Mr. J. GRIFFITH: Arrest of Development of Lens.

Mr. DOYNE: Retinal Hæmorrhages.

Mr. TREACHER COLLINS: Hæmorrhage into the Sheath of the Optic Nerve.

Mr. JESSOP: Detachment of the Retina.

Mr. HIGGINS: Two Eyes Lost by Spontaneous Hæmorrhage after Extraction of Cataract.

HUNTERIAN SOCIETY.

Sprains and their Treatment.—Pelvic Cellulitis.

AN ordinary meeting of this society was held at the London Institution, Finsbury-circus, on Jan. 27th, the President, Dr. HERMAN, being in the chair.

Mr. A. H. TUBBY read a paper on Sprains and their Treatment. He described the symptoms, differential diagnosis, and treatment. In the earlier stages—i.e., in the first three or four hours—he advocated cold and pressure and after that for three or four days the use of heat and pressure, and finally of well-directed friction and passive movements. If the joint remained stiff and painful liniments should be applied, but if it remained stiff only then massage and the application of the faradaic current were indicated.—Dr. F. J. SMITH thought that in some points the treatment of sprain was entirely different from fracture, although both were due to rupture, one of the soft parts and the other of the bones. He alluded to a point emphasised by Mr. Mansell Moullin—viz., if the patient was away from help the value of field or garden mould placed around the joint as a means of refrigeration and support.—Sir HUGH BEEVOR asked as to the treatment of sprains by massage within two days after the injury.—Dr. FORTESCUE FOX alluded to cases of chronic sprain complicated by teno synovitis. He was of opinion that in the case of the knee-joint the tender spot was just above, and to the inner side of

Hosted by Google

the insertion of the ligamentum patellæ. Dr. Fox was averse to treating most cases of sprain by rest, especially after middle life.—Dr. ETTLES alluded to the use of opium liniment, and doubted if any absorption of opium could take place.—The PRESIDENT alluded to cases of chronic weakness of the muscles around a joint—e.g., atonic flat-foot, some cases of scoliosis, knock-knee, &c. He asked as to the effect of rest in producing atrophy of muscles.—Dr. J. F. WOODS observed that he had in many cases removed the pain after sprains by "suggestion" and manipulation.

Mr. T. H. OPENSHAW read a paper on Pelvic Cellulitis. He quoted a case in which an abscess had been opened just internally to the anterior superior spine of the ilium and the cavity was found to extend to the pubes and down into the thigh. After four months the patient was discharged with a sinus. Mr. Openshaw also spoke of a second case in which the patient was discharged with a sinus, and of a third case which had healed after some months. He deprecated early surgical interference unless it were absolutely necessary, the points of urgency being implication of the skin and suddenly wide tracking of pus. Further, some cases got well spontaneously and others burst by themselves. He quoted five cases in support of his contention.—The PRESIDENT was disposed to leave matters much to nature. About half the cases suppurated, and nine-tenths of these opened just above, and to the outer side of, Poupart's ligament.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—Recurrent Appendicitis.

A MEETING of this society was held on Jan. 21st, the President, Mr. J. MACREADY, being in the chair.

Mr. W. R. H. STEWART showed a case of a man, aged twenty-three years, upon whom he had recently performed a plastic operation for a Deformity of the Nose. A cast showing the condition before operation was also exhibited. This showed a broad and deep groove in the middle line running from the lower end of the nasal bones downwards between the lateral nasal cartilages. The nose thus presented two well-marked tips. Along the floor of the groove there was a scar, and from this situation a tumour (a dermoid, it was thought) had been removed during infancy. At the operation it was found that the anterior margin of the septal cartilage was much broader than natural, and much of it, as well as of the lateral cartilages, had to be pared away before the sides of the cleft could be brought together so as to make the tip of the nose a single one. The result of the operation, six days after its performance, was very satisfactory and the patient's appearance was greatly improved.

Dr. ARTHUR WILSON read the notes of a case of Recurrent Appendicitis in a little girl aged five and a half years. There had been four attacks, two of them very severe, within five months, and about three weeks after the last subsidence of the inflammatory swelling the appendix had been removed by Mr. Mower White. The subsequent course of the case had been in every way satisfactory. The appendix showed considerable inflammatory thickening of its coats and three-eighths of an inch from the tip of it there was a marked constriction of its lumen. Distal to this the lumen was dilated into a small spherical cavity containing thick, purulent material and a semi-solid body, probably fæcal in nature. The mucous lining of the tube was nowhere ulcerated.—The PRESIDENT, Dr. STILES, Dr. GLOVER, Dr. TAIT, Dr. BAILEY, Dr. WATSON, and Mr. MOWER WHITE took part in the discussion which followed and Dr. WILSON replied.

Mr. PEYTON BEALE showed a male patient, aged twenty years, suffering from a Large Soft Swelling below the Calf of the Left Leg. The patient was the subject of congenital syphilis and had also a congenital malformation of the left tarsus and metatarsus. There was marked hypertrophy of the bones of the leg, the left leg being three inches longer than the right. The swelling was thought to be caused by lymphangiectasis, probably due to syphilitic fibrosis of the lymphatic vessels above. There was also considerable varicosity of the superficial veins of the leg and foot, no doubt due to partial blocking of some of the deep veins of the leg, also the result of syphilitic fibrosis.

Mr. BEALE also showed a man, aged forty-seven years, in whom he had excised the left elbow for tuberculous disease.[1] The point of interest in the case was the fact that excision of the same elbow had been performed thirty-six years ago at Bath so successfully that the patient had earned his living by hard manual work.

Mr. ALLAN HAIR, for Mr. TRAER HARRIS, exhibited a patient who, as the result of a blow, had sustained a double fracture of the body of the lower jaw. One fracture was just in front of the ramus of the jaw on the left side, and the other was between the two bicuspid teeth on the right. The fragments had been fixed by means of a Kingsley's splint, which the patient was still wearing eight weeks after the accident. There had been sequestra thrown off at the seat of both fractures and the septic condition of the mouth at the time of the accident had no doubt, in spite of the free use of 1 in 60 carbolic lotion since, tended to delay the union of the fragments.

ÆSCULAPIAN SOCIETY OF LONDON.

Rodent Ulcer.—Perforating Gastric Ulcer, Laparotomy, Recovery.—Gastric Ulcer with Probable Adhesions.—Senile Endometritis.

A MEETING of this society was held on Jan. 22nd, Mr. STEPHEN PAGET, President, being in the chair.

Mr. G. DENTON showed a patient, a woman aged fifty years, suffering from Rodent Ulcer of the Cheek. The sore, which was of three years' duration, was of the size of a florin and had penetrated nearly to the mucous membrane. No operation was allowed.

Mr. A. Q. SILCOCK read notes of a case of Perforating Gastric Ulcer in which Laparotomy had been performed with a successful result. A young unmarried woman was suddenly seized with symptoms suggesting gastric perforation. After twenty-four hours she was taken to St. Mary's Hospital. Mr. Silcock opened the abdomen in the left epigastric region and found on the anterior wall of the stomach towards the cardiac end a perforation from which the contents of the organ had escaped freely, setting up peritonitis. Stitches inserted would not hold, but tore their way through the dense tissue surrounding the opening. A considerable fold of the stomach wall on either side was therefore taken up and the reef or tuck thus made secured by stitches (a method also practised by Mr. William H. Bennett in the treatment of dilated stomach). The peritoneal toilet was performed of neeessity somewhat hastily and imperfectly, a gauze tampon was inserted, and the abdominal wound closed except at the point of its egress. The patient recovered without a bad symptom. (A fuller account of this interesting case will shortly be published in our columns.)

Dr. B. G. MORISON read notes of a case of Hæmatemesis occurring in a subject of chronic dyspepsia and attributed to gastric ulcer. The concurrence and continuance of fever (temperature 101° F. falling to 99·8°), previously absent and unexplained by any other defined cause, suggested the formation of local adhesions.

Dr. L. DURNO read notes of two cases of Senile or Post-climacteric Endometritis. The patients, aged respectively sixty-four and sixty-five years, had ceased to menstruate from twelve to fifteen years previously. In both cases slowly progressive emaciation was associated with a more or less thick and offensive discharge, a tender vagina ulcerated here and there, and enlarged uterus with smooth interior. Rest, tonics, and swabbing the endometrium, in one case with nitric acid and in the other with iodised phenol, followed by vaginal douches, effected a cure in from two to three months. Dr. Durno discussed at length the differential diagnosis between this class of cases and malignant disease of the uterus.

LIVERPOOL MEDICAL INSTITUTION.

Abdominal Hysterectomy.—Castration for Enlarged Prostate.—"Saddle Nose" remedied by Celluloid Bridge Permanently Buried.—Thoracic Aneurysm.—Suppuration in the Small Omental Sac.—Unsuccessful Attempt to Ligature the Left Subclavian Artery.

A MEETING of this society was held on Jan. 28th, Dr. RICHARD CATON, President, being in the chair.

Dr. BRIGGS exhibited specimens from four cases of

[1] This case was reported fully in THE LANCET of Jan. 30th, page 310.

Hosted by Google

Complete Abdominal Hysterectomy, in each of which cases there were serious symptoms calling for operation.

Mr. ROBERT JONES related four cases of Enlarged Prostate with Urinary Complications upon which he had operated with success. In the first two cases both testes were removed, in the third the vas was divided and the lower end turned into the wound, and in the fourth one testis was removed. The first patient, aged sixty-five years, has led catheter life for five years. Before operation the prostate was the size of a hen's egg. Six weeks after the operation the catheter was discarded and the prostate was half its normal size. The second case was one in which the patient, aged sixty-seven years, had a very much enlarged prostate. He had had urinary difficulties for years and suffered retention for six weeks. Double castration was performed and he was in two months able to dispense with the catheter and was now practically well. In the third case the vas was divided and turned into the wound. Considerable amelioration of symptoms took place. In the fourth case the operation was only performed three weeks ago, and the prostate is now softer and less prominent. The symptoms have undergone amelioration.—Dr. ALEXANDER, Mr. RUSHTON PARKER, and Mr. LARKIN made remarks favourable to the operation.

Mr. THELWALL THOMAS brought forward a girl, aged fifteen years, in whom he had operated seven months previously for the deformity known as "Saddle Nose." The nasal bones had disappeared in childhood from congenital syphilis. A piece of celluloid modeled like the nasal bones and possessing a well-marked keel on its concave surface was inserted subcutaneously and pressed into position, the keel fitting between the nasal processes of the upper jaws, the lateral portions resting upon these processes. The incision was made on the left side and closed with horse-hair sutures. The embedded celluloid does not appear to cause any irritation, and has of course greatly improved her personal appearance. The above device was adopted in place of the osteo-periostic flap methods that have from time to time been described, but which all leave well-marked cicatrices elsewhere.

Dr. GLYNN showed a patient suffering from Thoracic Aneurysm in whose case the diagnosis was attended with more than ordinary difficulty. The patient came to the Royal Infirmary with blocking of the external jugular vein. On careful examination it was found that he had a thoracic aneurysm. There were, however, several peculiarities in the case. In the first place there was no pain, a symptom which Dr. Glynn considered very constant in thoracic aneurysm. However, on bending down the patient's face flushed, there was tracheal tugging, there was no fremitus over the left side of the chest, there was no pulsation in the left carotid, and the radial pulse on the left side was small. Dr. Glynn pointed out that the loss of fremitus was one of the earliest signs of aneurysmal pressure in the thorax.—Dr. WALLACE and Mr. RUSHTON PARKER commented upon the case.

Mr. BANKS related the case of a girl who had Suppuration in the Small Omental Sac. The girl was hit in the abdomen by a "swing boat." There was a central abdominal swelling reaching from the xiphoid to the umbilicus. There were pain, vomiting, high fever, and want of sleep. On examination there was a doubtful sense of fluctuation and from the history a blood tumour was diagnosed. An incision was made in the middle line of the abdomen above the umbilicus. The great omentum spread over the tumour; a trocar was introduced into the tumour and thin, greenish, fluid escaped. A large tube was substituted for this and after many weeks' drainage the patient recovered. The fluid withdrawn was old blood on the point of suppuration.

Mr. BANKS also brought forward the case of a man aged twenty-seven years in whom he had attempted to Ligature the first portion of the Left Subclavian Artery. The man had been severely crushed by an engine ten weeks before admission to hospital. The accident caused, among other injuries, a fracture of the outer third of the clavicle. The patient stated that immediately after the accident a swelling the size of a cocoa-nut appeared in the posterior triangle of the neck; this got smaller, but had re-commenced to grow. The diagnosis made was aneurysm of the second or third portion of the left subclavian artery. The operation to apply a ligature to the first portion of the artery was attempted; a long incision down the middle line of the neck was made; a transverse incision at either end of this enabled a flap to be dissected and turned outwards; the clavicle was cut through and the inner third removed; a piece of the first rib was also cut away to enlarge the field of operation; the interna jugular and innominate veins were tied; the left subclavian vein caused some trouble and was plugged with cyanide gauze; the aneurysm did not pulsate much, and this want of pulsation increased the difficulty of finding the artery. During the prolonged operation the left pleura was opened and was plugged with gauze. The difficulty of the operation was graphically described by Mr. Banks, and it was at last deemed necessary, on account of the condition of the patient, to desist from further attempts to secure the vessel. The patient died seventeen days later from pleurisy.—Mr. PAUL and Dr. ALEXANDER commented upon the enormous difficulties of the operation.

PATHOLOGICAL SOCIETY OF MANCHESTER.

Exhibition of Specimens.

A MEETING of this society was held on Jan. 20th, Mr. WILLIAM THORBURN, Vice-President, being in the chair.

Mr. PETER THOMPSON showed a specimen of Polypoid Growth in the Duodenum. The tumour, which was about the size of a walnut, was attached to the region of the pylorus and possessed a well-marked pedicle, from which it hung freely in the interior of the gut. Continuous with the pedicle was a mass of hypertrophied mucous membrane, which microscopical examination showed to be partly gastric and partly duodenal in character. The gastric portion extended through the pylorus into the stomach, where it was continuous with the general lining mucosa, and this mass almost entirely occluded the passage. By experiment it was found that a very small stream of water could pass from the stomach onwards. There was in addition a small intussusception of the pyloric end of the stomach into the duodenum. The specimen was obtained from a dissecting-room subject aged seventy-five years, and the clinical history available shows that the tumour gave rise to no symptoms during life. It would appear that polypi in the region of the pylorus are rare, and it is still rarer that they should be determining factors in the production of intussusception so high up in the alimentary tract. Microscopically the polypus was found to be fibro-adenomatous in nature.

Dr. ERNEST S. REYNOLDS showed a specimen of an Aneurysm (arising from behind the aortic valves) which projected into the Right Auricle, where it had ruptured suddenly by a slit-like aperture. The aneurysm was the size of a hazel nut, and two of the aortic valves had been thrown into one, possibly from old endocarditis. The specimen was obtained from the body of a girl aged seventeen years who had had no known previous illness, but had died quite suddenly whilst walking in the street.

Dr. LEA showed the Brain from a girl aged twelve years into which an extensive Intra-ventricular Hæmorrhage had occurred, resulting in rapid death. The patient had enjoyed good health and had not suffered from any serious illness. The family history was good; there was no history of syphilis. A few hours before death she complained of headache, and vomited several times. She then went to bed, and was found dead two hours later. No convulsions were observed. The necropsy showed that the thoracic and abdominal viscera were healthy. The brain externally appeared to be normal. There were no signs of meningitis. On section the left ventricle was found to be distended with blood clot, the septum lucidum had ruptured, and some blood had passed into the right ventricle and also into the third ventricle. There was no laceration of the basal ganglia, and the bleeding appeared to have been primarily in the ventricle. There was no tumour. Sections were made of the small cerebral arteries; these, however, were quite healthy. It is possible that the hæmorrhage may have been due to a ruptured vein of the choroid plexus. In rare instances aneurysms have been known to rupture in young subjects. The precise seat of the hæmorrhage could not be discovered in this case.

PLYMOUTH MEDICAL SOCIETY.

The Present Position of Serum Therapeutics.

AT a meeting of this society held on Jan. 28th Dr. WEBBER read a paper on the Present Position of Serum Therapeutics. After a brief consideration of the history and

Hosted by Google

principles of serum treatment and the methods of preparation of the antitoxic serums Dr. Webber discussed the results of the treatment in several of the diseases to which it has been applied. (*a*) In diphtheria its success was held to be firmly established. The statistics of Goodall, Von Ranke, Baginsky, Welch, and the committee of the American Pædiatric Society, showing an average death-rate under the treatment of 17·1 per cent., were compared with the average death-rate under former methods of treatment, estimated at 40 6 per cent. Having considered the beneficial influence of the injections on the clinical course and complications of diphtheria, the effect of the antitoxin on the kidneys was examined, and having regard to the small number of cases in which nephritis (as shown by the presence of blood and casts in the urine) had been recorded while under the treatment, and to the fact that it was frequently doubtful whether such nephritis was really caused by the serum or was due to the diphtheritic process itself, it was held that such occasional and uncertain evidence of harmful effect of the serum should not be allowed to militate against its general use. (*b*) In tetanus the results were not found to be so satisfactory. After allusion to the statistics published by Kanthack and by Hewlett, Dr. Webber examined the reports of twenty-four cases of antitoxic treatment of tetanus recently published. Of these he found that twelve recovered and twelve died, and confirmed the deductions of Kanthack, that the beneficial effects of serum injections were more frequently observed in the chronic cases with long incubation period than in those with short incubation and rapid onset of spasms. Dr. Webber referred to the strong immunising power of tetanus antitoxin when used as a prophylactic agent and its successful use in this manner in veterinary practice, and concluded that the serum treatment of tetanus, though not so successful as could be wished, still deserved an extension of trial. (*c*) The results of injections of anti-streptococcic serum in pyogenic affections were next considered, and a brief account of the cases reported up to the present was given. It was held that the successful results published in several of the cases, notably in puerperal septicæmia, urged the continuance of its use. (*d*) The treatment of inoperable malignant disease by injections of the mixed toxins of streptococcus erysipelatis and bacillus prodigiosus was reviewed, with special reference to Coley's work and to his publication of 160 cases treated by this method.[1] Though the constitutional effects on the patients were shown in many cases to be severe (rigors, pyrexia, and emaciation being often, and even a fatal result occasionally, observed), yet in view of the desperate nature of the diseases to which it was applied a further trial of the method was recommended. (*e*) The results of the injection of Maragliano's anti-tuberculous serum as published abroad were discussed, and, having regard to the encouraging statistics recorded by him, it was hoped that the method would receive a share of attention in this country. The paper concluded with a brief reference to Kitasato's work on anti-cholera serum and to that of Calmette and of Fraser on antivenene.

Microscopic slides of the bacilli of diphtheria, tetanus, and tubercle and of pure cultures of streptococci (kindly lent by Dr. Pethybridge) were shown.

[1] American Journal of the Medical Sciences, September, 1896.

THE ROYAL UNITED HOSPITAL, BATH.—The annual meeting of subscribers of this institution was held on Jan. 25th under the chairmanship of the Mayor. The seventy-first annual report showed that the patients treated during the past year had numbered on the medical side 685, on the surgical 663, making a total of 1348, as against 1387 in 1895. The out-patients numbered 9698 as against 9912. The expenditure had amounted to £6656 as against £6248 of the previous year, the increase being due to the opening of a new isolation ward and repairing the outside of the whole building. The income showed a falling off, as compared with 1895, in subscriptions of £35, while donations had been less by £414. Collections in churches and chapels were £112 lower. A substantial increase was shown in workmen's collections, but had it not been for a very much increased receipts from legacies the financial report would have shown a great deficit. As it was, the year's work showed that the income had failed to meet the expenditure by £229.

Reviews and Notices of Books.

Injuries and Diseases of the Genital and Urinary Organs. By HENRY MORRIS, M.A., M.B. Lond., F.R.C.S. Eng., Surgeon to the Middlesex Hospital, Member of the Council and of the Court of Examiners of the Royal College of Surgeons of England, Examiner in Surgery in the University of London. Pp. xvi. and 478. With 97 Illustrations. London: Cassell and Co. 1895. Price 21*s*.

THE title of this work is hardly an exact indication of the contents, as it deals with the injuries and diseases of the genital organs of the male only, and with the bladder in both sexes, while the injuries and diseases of the kidney are not included at all. Undoubtedly it was difficult to express this in a short title. The forty-seven chapters which the volume contains are divided into three sections; of these, the first treats of the male genital organs, the second of the organs which belong both to the genital and to the urinary systems, and the third section is concerned with the urinary bladder.

In speaking of diseases of the scrotum Mr. Morris distinguishes between lymph scrotum and elephantiasis scroti, but the two are surely nothing more than slightly different manifestations of one condition—namely, obstruction to the return of the lymph of the part. In the treatment of lymph scrotum excision is recommended, but it is not mentioned that those surgeons who have had most experience in the operative treatment of this disease consider that it is generally unadvisable to attempt to remove the enlarged inguinal lymphatic glands, as in most cases they contain anastomotic channels by which the lymph is able to return, though its ordinary course has become obstructed. Mr. Morris considers that "chimney-sweep's cancer" is much less often met with now than formerly. It is difficult certainly to come to a trustworthy decision on this point, but some careful investigators are of opinion that there is no definite evidence that the disease is any less frequent now than it was.

The congenital abnormalities of the testis are well treated, the author following the classification of Le Dentu. An interesting account is given of the somewhat rare condition called "Torsion, or Axial Rotation of the Spermatic Cord," first described by M. Nicoladoni in 1885. Torsion is much more likely to occur when the testis is retained, but it is by no means limited to undescended or misplaced testes. Various causes have been suggested for this accident, such as the absence or excessive length of the mesorchium, or violent twists, but in many cases no adequate cause seemed to be present. The symptoms closely resemble those of a strangulated hernia, and the true nature of the swelling has in several of the cases been discovered only after an exploratory incision. Puncture of the testis, Mr. Morris tells us very emphatically, should never be performed, except with the object of evacuating pus, and he considers that it is unjustifiable in an orchitis or epididymitis where suppuration has not occurred. In the orchitis of mumps the author points out that it is the body of the testis which is affected and that the epididymis is very rarely involved; he further remarks that the orchitis only occurs in boys and adults in whom the testis is capable of functional activity, and it is never seen in children or old people in whom the testis has either not yet assumed or has lost its secretory powers. Atrophy is not so commonly a result of this form of inflammation as it is usually thought to be. Orchitis is also described as occurring during tonsillitis, typhoid fever, scarlet fever, small-pox, influenza, ague, and gout. It is, of course, important to bear in mind that in some of the cases of orchitis occurring during the course of any of these diseases it may be the result of the employment of a catheter.

In the treatment of hernia testis Mr. Morris has obtained

Hosted by Google

excellent results by excising the herniated structures and uniting the scrotal tissues over the opening. Hydrocele of a hernial sac is usually considered to be very rare, but the author states that it is by no means uncommon, and that he operated upon three cases within a few weeks of each other. Mr. Morris gives notes of a unique case of cavernous venous angiomata of the spermatic cord; the patient was twenty years of age and had several hard painful lumps along the left spermatic cord; these were removed by operation and were found to be cavernous in structure and to contain blood, while some had become cystic; the patient recovered. In the treatment of varicocele Mr. Morris prefers the subcutaneous ligature, two or three ligatures being applied, and he considers that this method is as effective as excision, and that it is preferable because it needs no open wound—a great advantage in a part not always easily kept aseptic. He has not seen recurrence occur if the ligatures are tied tightly and are applied sufficiently high up and low down, and if the patient is kept in bed for two or three weeks after the operation in order to allow the coagula to become organised. He thinks there is but little risk from puncture of a vein if care be taken that the ligatures are aseptic.

In strictures in the bulbo-membranous part of the urethra, which do not require external urethrotomy or perineal section, Mr. Morris considers that Holt's dilator is an excellent instrument when properly used; the dilatation must be done by a graduated series of tubes (about eight in number), and these must be pushed quickly through the stricture one after the other. When used in this way he has never seen any harm result and he thinks that no laceration of the stricture takes place. This method is a very different one from that in which Holt's dilator is usually employed, and which has led to many unfortunate results. Whatever method be used, it is, as Mr. Morris points out, of great importance that complete dilatation be effected at a single sitting so that a free outlet may be afforded to the septic contents of the bladder. For cases in which external urethrotomy is required, and in which Wheelhouse's operation would prove difficult, tedious, or impossible, Mr. Morris has found the following plan answer admirably. He employs a straight tapering staff, to the end of which is attached a filiform guide bougie. The guide is introduced into the bladder, and the staff, having been pushed as far as it will go, is cut down upon from the perineum and the front part of the stricture divided; the point of the staff is pushed onwards and the whole stricture is cut through, the knife running in the groove. This method saves the trouble of searching for the anterior end of the urethra in a bleeding wound. Mr. Morris also thinks highly of Cock's operation, but he always, either a few days after the operation, or more usually at the time of the operation, cuts through the cicatricial tissues and leaves a catheter in her bladder.

In cases of hypertrophy of the prostate requiring operation Mr. Morris is inclined to prefer a perineal incision, by which partial prostatectomy can be performed without opening either the urethra or the rectum. We are told on page 348 that "incontinence from atony or paralysis will be often rapidly cured by electrolysis applied to the hypogastrium or even within the cavity of the bladder," but no further information is afforded as to how the current, or even what current, should be employed. That such a good result should be often obtained is hardly the experience of the majority of surgeons.

Taken as a whole, the book may be considered a valuable addition to the literature of the subject of which it treats, but we cannot hide from ourselves the fact that flaws exist in it which should have no place. When a book is written by an acknowledged leader of surgery such as Mr. Morris is, the surgical public has a right to expect that in it, not merely shall the extensive knowledge and ripe experience of its author be conspicuous, but also that it shall have been written with due care and with a full sense of the importance of every word employed, for those who are unable to judge for themselves will rely on its statements, taking them on the credit of Mr. Morris's name. But what do we find? We put aside such misprints as "ilium" for "ileum" on page 131, where a diagram is said to illustrate a "hernial sac containing ilium," or the mis-spelling "phymosis" at least twice—these may be the fault of the proof-reader though we venture to think that they should not have escaped the author's attention; but we also find statements to which we must take exception. For instance, on page 164 we are told that numerous evil results may follow phimosis. Among others we find "simulated or actual hip disease and talipes." That simulated hip disease may occur with phimosis we do not question, but we should like very much to know how it is possible for "actual hip disease" and "talipes" to result from a narrowed foreskin. If Mr. Morris has met with cases demonstrating the occurrence of such an astonishing result, surely he should bring them forward, and not leave such a statement unsupported by any proofs. Mr. Morris is examiner to the University of London; how many marks would he give to a candidate who suggested "hip disease and talipes" as results of phimosis?

Although the author in his preface explains that in order to make his descriptions as brief as possible he has, in reference to operative treatment, generally confined himself to principles, yet we must confess that in numerous instances throughout the work the descriptions of operations are so brief as to be practically worthless. We hope that Mr. Morris will not think that we fail to appreciate the great value of his book; we appreciate it to the full, but we cannot be blind to the faults it contains.

Gout and Goutiness and their Treatment. By WILLIAM EWART, M.D. Cantab., F.R.C.P. Lond., &c., Physician to St. George's Hospital and to the Belgrave Hospital for Children. London: Baillière, Tindall and Cox. 1896. Pp. 589. Price 12*s.* 6*d.*

THIS is a work which will thoroughly repay perusal by those who have the necessary time to devote to it. The author apologises in the preface for the bulk of the book, which, he says, is not the least of its faults. It is, in our opinion, the only serious fault to be found with it, and it depends upon a certain diffuseness of style and arrangement perhaps especially difficult to avoid in the treatment of such a subject as gout. The book would not lose in value, and it might gain very considerably in some respects, by a judicious compression to some two-thirds of its present size. Having said this, it must be admitted that the work is a very able and thorough review of the subject and presents a happy blend of old-fashioned physic—in its best sense—with the most recent advances in pathology and therapeutics.

The book falls naturally into two parts. The first deals with the chemistry, morbid anatomy, and pathology of the disease, with the theories which have been advanced as to its nature and with its clinical phenomena. The second deals with treatment, and this part comprises the special task which the author has set himself to accomplish, though we find it difficult to say which portion is the better. The literature of gout is very voluminous, and Dr. Ewart presents us with an excellent account of the various theories and opinions which have been held on the subject from the earliest times. These, critically reviewed in the light of modern pathological research, form an admirable introduction to the therapeutical discussion which occupies the latter part of the work. Just emphasis is laid on the distinction between goutiness and declared gout, and throughout the book the line is clearly drawn between the two conditions; the original gouty defect is well defined as "a functional derangement fraught with

Hosted by Google

organic consequences." Free and good use is made by the author of the writings of his predecessors, particularly of those of Sydenham, Garrod, Duckworth, and Roberts. The chemical researches of the last named on uric acid necessarily receive full consideration, and the views of Dr. Haig, in part accepted, are the subject of judicious and able criticism. Though it may be true that "without uric acid, no gout," yet Dr. Ewart is far from admitting that the essence of goutiness is merely uric acid. Of greater moment are the antecedents of the uric acid excess. From this point of view the recent researches of Horbaczewski on the derivation of uric acid from nuclein and its relation to leucocytosis receive very careful attention, and much weight is attached to them. As regards the renal theory of gout Dr. Ewart epigrammatically observes: "In the result the kidney is inadequate to the circumstances; nevertheless the change may be in the circumstances rather than in the kidney." The liver, in his opinion, though sharing in the general metabolic disturbances of gout and, indeed, taking a prominent part in them, has actually a doubtful part in its etiology. He is unable to accept the nervous theory of gout in its entirety. Though the nervous system may influence faulty metabolism, he considers that it does so in the degree only in which that system itself suffers from the effects of perverted nutrition. No theory of his own is put forward by the author; nevertheless, the summary and critical review of existing theories is a valuable contribution to the literature of gout.

In discussing the treatment of the disease the same broad distinctions are drawn between gout and goutiness. Gout is curable, though some of its worst results are not. Recent advances in pathology—and Dr. Ewart maintains that pathological facts must be the proper basis of treatment—render needful a re-consideration of some of the principles which have hitherto been recognised in its therapeutics. Space fails us to follow the author in detail into the critical review of the various modes of treatment which have been advocated. Colchicum and the alkalies naturally take the first place, and the remarks on the salicylate treatment of gout appear to us peculiarly valuable. Local treatment and diet receive full attention and several chapters are devoted to the medicinal springs which enjoy repute. The hygienic and prophylactic treatment of the disease are also ably reviewed. The whole question is, indeed, discussed in a masterly and scientific manner and the book cannot fail to impress the reader by the exhaustive manner in which Dr. Ewart has treated a difficult subject and the critical acumen which he has brought to bear upon it.

We cannot refrain from one trivial comment in concluding. In a footnote on page 14, dealing with the advantages of a knowledge of Greek in medical nomenclature, the author shows himself, as we had thought, somewhat of a purist. Yet he stoops later to the employment of that deplorable and barbarous word "uricacidæmia," against which no possible protest can be too strong.

LIBRARY TABLE.

De la Nature de l'Épilepsie. (*The Nature of Epilepsy.*) By FR. HALLAGER. Paris: Société des Éditions Scientifiques. 1897.—This work is devoted to an inquiry into the causation of epileptic attacks. A well-arranged account of the experimental evidence is given, followed by a chapter on epileptiform seizures. This is accompanied by a very useful table of seventy cases in which such seizures were due to local disease. A chapter is devoted to "reflex epilepsy," and forty-six supposed cases from medical literature, but their epileptic nature is in some cases hardly supported by the symptoms described. A description of post-epileptic states follows, and much stress is laid by the author on a single observation made by Dr. Hughlings Jackson on the changes in the retinal circulation seen through the ophthalmoscope during and after a fit. After briefly reviewing the points which favour his theory Dr. Hallager comes to the conclusion that "there are no phenomena of epileptic origin which do not find their explanation in the theory of anæmia," this anæmia being a local or general one in different circumstances. The evidence adduced, however, supports the view that the anæmia is not causative but concomitant quite as well as it does the author's theory. The book is well arranged and clearly written, and the tabulated abstract of nearly a hundred published cases will be found useful by those wishing to refer to the subject.

Recherches Cliniques et Thérapeutiques sur l'Épilepsie, l'Hystérie, et l'Idiotie. Par Dr. BOURNEVILLE. (*Clinical and Therapeutic Researches on Epilepsy, Hysteria, and Idiocy.* By Dr. BOURNEVILLE.) Vol. XVI. Thirty-one Figures in the text and Eight Plates. Paris: Felix Alcan. 1896. Price 7 francs.—This annual report of the Bicêtre Hospital for Idiots at Paris contains, as usual, much interesting material. It commences with an account of some of the educational methods employed and a general report of the working of the institution during the year. The second part is devoted to clinical descriptions of the more important cases. These are well illustrated by photographs. There is a full pathological report of the cerebral conditions in many patients that have died. Therapeutics are not forgotten. Further examples illustrative of the value of thyroid extract in some cases of obesity and in cretinism are given. There is a full consideration of the value of bromide of camphor as a nervous sedative, its use in cases of vertigo being strongly recommended by Dr. Bourneville.

JOURNALS AND REVIEWS FOR FEBRUARY.

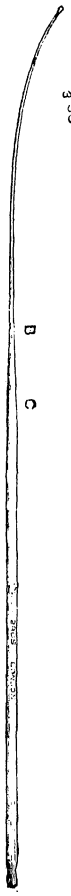
Edinburgh Medical Journal.—The opening paper is by Mr. Jonathan Hutchinson and describes (1) a case of Hypertrophy of the Gums with General Dwarfdom; (2) the Malformations of the Teeth caused by giving Mercury to Infants; and (3) the Present Position of the Leprosy Problem. He states that mercury given to a pregnant woman will cause the milk teeth of her child to undergo caries soon after being cut, and that mercury given to an infant will produce a characteristic injury to the enamel of the permanent teeth. Dr. R. Milne Murray (Edinburgh), writing on the Deflection and Rotation of the Pregnant Uterus, suggests that rotation may offer a mechanical explanation of deviation. In his experience deviation is almost always to the left when the fœtus is in the occipito-posterior position, and there is an approximate numerical coincidence between the proportion of cases of these two conditions. Dr. Veitch and Dr. Fowler each describe a case in which Puerperal Septic Infection was successfully treated by Anti-streptococcic Serum. Altogether there are twelve original articles.

The Contemporary Review.—Mr. W. H. Dickinson treats the question of the water supply of London from a somewhat novel point of view. He finds that if a table showing the dividends declared last year by the respective companies be examined side by side with the number of microbes found per cubic centimetre of the respective waters provided by these companies the following rule may be established:—"The amount of dirt and number of microbes in London drinking-water may vary inversely as the profits derived by the companies supplying it." This argument should have been carried further by quoting similar statistics in regard to the water-rates and microbes of those supplies that are now under public control.

Chapman's Magazine.—The February number of this magazine has an admirable story by a new writer, Alan Oscar.

Hosted by Google

It is called "Captain Kidd's Millions," and treats of that well-known character from a different point of view to that generally taken. The writer makes good use of the feeling that everyone has experienced at some time or other—namely, the consciousness of pre-existence or "the having been there before,"—a curious psychological state the study of which has always been a favourite subject both with poets and medical men. Henry Vaughan, who was both, and Rossetti, in the lines—



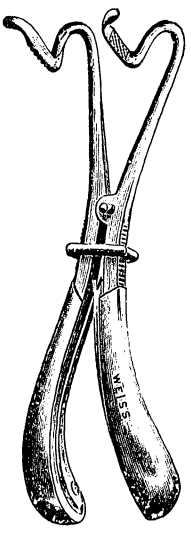
> "I have been here before,
> But when or how I cannot tell;
> I know the grass beyond the door,
> The sweet, keen smell,
> The sighing sound, the lights around the shore"—

have treated of this state. The whole matter was handled in a masterly way by Sir James Crichton-Browne in his Cavendish Lecture.[1] Another feature of the story is a most vivid picture of Execution Dock. The lower reaches of the Thames were not thickly populated in the eighteenth century, otherwise we might speculate on the dangers to health which would arise from the presence of so many putrefying bodies hanging in open air, even though, as in the "Fairchild Family," the sight of them served as correctives to the hasty tempers of youth.

New Inventions.

A DILATING URETHRAL BOUGIE.

THE favourable experience which I have had of the dilating bougie now described induces me to bring it under the notice of my medical brethren. It is made of whalebone and is about 35 cm. (14 in.) long. The slender extremity A B measures about 12 cm. (4¾ in.) in length, and is as thin as an ordinary bougie with a bulb-shaped point; this portion may be either bent (*coudée*) or twisted so as to more easily enter a stricture, and may be called the guide. The dilating part of the bougie, where it gradually increases in diameter until the full thickness is reached, is at B C, and is about 3 cm. (1¼ in.) long. The remainder of the instrument is of uniform diameter and measures about 20 cm. (8 in.) in length; this part is made in three different sizes corresponding to Nos. 2, 3, and 5 of the English scale, the guide being of almost the same diameter in all three sizes. Guides are adapted to various other instruments, such as catheters, stricture dilators, urethrotomes, &c., and when they are made of whalebone they are not different from those of my dilating bougie; but in those instruments the guide generally forms a continuation of a metallic tube or rod, an arrangement which is deficient in flexibility and has the further disadvantage that the instrument does not always follow the guide when the stricture is very difficult. If made in elastic gum the guide bends as soon as it comes in contact with an obstruction and is too flexible to pass through difficult strictures. As the dilating bougie is made entirely of whalebone the flexibility of the guide diminishes gradually, and there are no abrupt thickenings such as are found in some cases where the guide is attached to metal. Consequently when the guide has passed through a difficult stricture the dilating part B C must necessarily follow. An experience of more than eleven years has convinced me of the advantages of this bougie in the dilatation of difficult strictures.



Rome. DR. NATALE AMICI.

[1] THE LANCET, July 6th and 13th, 1895.

THE "MAMMOTH-TUSK" GAG FOR SENILE AND EDENTULOUS JAWS.

ALL the gags I have hitherto met with are very prone to slip, thus embarrassing the operator and often seriously deteriorating his results. Messrs. Weiss and Son, of 287, Oxford-street, W., have kindly made for me the instrument here depicted, which I find most valuable for tongue and mouth operations generally; specially so, however, when the jaws are senile and edentulous. It is the familiar Ferguson's gag with a slight modification consisting in a prolongation of the prongs, which are also curved outwards at an obtuse angle and bevelled. When in position they lie—sheathed, of course, with vulcanite—on the inner aspect of the gum, and cannot well slide off until deftly removed. The instrument must be introduced with the handle in a line with the patient's neck, then rotated until the latter is at right angles to the trunk, and the jaws prised open, being extracted by a repetition of the same manœuvre. The head, if not over the table edge, should be turned on one side, the handle of the gag lying on the uppermost cheek. A remote suggestion of the recurvation in the mammoth's tusks explains the choice of title.

HERBERT SNOW.

Gloucester-place, Portman-square, W.

THE PROPOSED NEW PORTSMOUTH HOSPITAL.—A most promising beginning was made at Portsmouth on Friday with the scheme which has been discussed for some weeks for the erection of new hospital accommodation as a commemoration of the longest reign in English history. The meeting was called by the Mayor (Mr. G. E. Couzens) and was most representative in every sense; the mayor mentioned that the foundation stone of the present institution was laid by the late Prince Consort. Sir John Baker, M.P., the senior representative of the borough, moved a resolution favouring the erection of a new block of wards "in view of the general enlargement and improvement of the institution," and promised £500. Alderman Sir William King seconded and offered £100. Before the meeting ended nearly £2500 was subscribed, the mayor giving £250. As the present accommodation for males is but 32 beds—16 for regular and 16 for casual patients—it is probable the new wing will be for males.

THE SOUTHAMPTON SLUM SCHEME.—After some trouble the Southampton Corporation have acquired the property on the condemned area which by special Act of Parliament they intend to clear. The claims made for compensation totalled £42,088, which sum has been reduced by arbitration to £28,762, a difference of £13,326. The area first to be cleared—that between Simnel-street, Pepper-alley, Blue Anchor-lane, and the Old Walls—it will be necessary to replace with sufficient buildings to accommodate 250 persons of the working-classes before the remainder of the area is cleared. Mr. Harris, the medical officer of health, has put forward a scheme for this re-erection which includes a municipal common lodging-house upon the lines of the Rowton lodging-houses in London, modified to suit the purse of the Southampton Corporation. A rough estimate by the borough surveyor puts the cost of such a house to accommodate 240 single men in separate cubicles at £8500. As to artizans' dwellings, those recently erected by the Manchester, Sheffield, and Lincolnshire Railway Company in St. John's Wood are suggested as patterns. A building containing twenty sets of these flat tenements would, it is thought, cost £5000 and produce (at 5s. 6d. weekly each) an annual rental of £286. An Elizabethan house has unfortunately been condemned, but efforts are being made to preserve an ancient vault in Simnel-street.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 6, 1897.

RUMOURS and suggestions of a gigantic scheme for collecting money for the benefit of London hospitals still continue to fill the air. Sir WILLIAM BROADBENT'S allusion to these in his speech at the Charity Organisation Society could scarcely be merely casual. The idea is too natural and too agreeable to human nature in its moods of gratitude and joy to be lightly dismissed. HER MAJESTY has given it to be understood that while she will fall in with any methods of commemoration that commend themselves to her grateful and loyal people she would be especially pleased with measures that contemplate the benefit of the sick poor. The General Committee appointed in connexion with the draft scheme for a Central Hospital Board is to hold a first meeting to-day (Friday), and we understand that the members will take into consideration the possible event of the creation of a fund in aid of the hospitals of London, and will consider a proposal to address a communication on the subject to His Royal Highness the PRINCE OF WALES. There is no time to lose if such a fund is to be created, and there is no body that can more fitly undertake its promotion than the committee nominated at the recent meeting held under the auspices of the Charity Organisation Society. This committee will have no mere individual institution in view. It is the hospitals as a whole, as a system, the hospitals detached from their abuses that must be considered, and it would be difficult to name any other body with more knowledge and more intelligence to discharge such a function. The Charity Organisation Society itself will immensely enhance its own usefulness by doing all in its power to promote the organisation of a scheme for the aid of the hospitals. In the very nature of things this society has had to be somewhat critical in its action, so much so that many people have come to think its action is all criticism. It has a duty laid upon it in this sixtieth year of the reign of Her Majesty Queen VICTORIA, and that supreme duty is to devise and promote not only means for dispensing charity rightly, but ways for providing the very funds themselves. We have already expressed our approval—not in detail, but in general—of the scheme for the promotion of a Central Hospital Board for London. The one weak point in the claim of the society is that it has never been conspicuously associated with means for helping the hospitals out of their straits. To organise a fund in this memorable year for their special relief will be to develop a new function and a new claim to the gratitude and confidence of the public. Whatever measures may be necessary for the reform of hospital abuses must be accompanied with unmistakeable proofs of goodwill to hospitals themselves so far as they minister to the really necessitous sick. For the sake of the hospitals, as well as for that of the committee proposed by the Charity Organisation Society, we are glad to learn that it is in contemplation promptly to discuss this Commemoration scheme of a Fund for the Aid of London Hospitals. The very size of London puts it at a disadvantage as compared with smaller communities. A provincial town has its one or two institutions which everybody sees and knows. Here we have nearly two hundred, the great majority of which are mere names to those who are expected to support them To link the name of HER MAJESTY and her glorious and sympathetic reign with a fund for the relief of the hospitals of London will be to band the hospitals into one great cause which will appeal more powerfully than anything else to all ranks and classes of HER MAJESTY'S metropolitan subjects. We are glad that the committee appointed at the meeting of Jan. 25th is to consider this great subject mooted in the speech of Sir WILLIAM BROADBENT.

There is an obvious want of one great single purpose upon which to concentrate the sentiment of the metropolitan community. Here is such a purpose. And the acceptance of it by His Royal Highness the PRINCE OF WALES on behalf of HER MAJESTY would fill the hearts of hospital authorities with new hope. The response in our opinion would be all the more hearty and generous if the fund so created were to be entrusted to a committee which by its very constitution was known to be favourable to keeping hospitals to their proper and original function.

In any case the subject is one that requires most careful consideration, and one important point to be decided is whether the relief to be granted is to be organised for this year only or whether there is to be any idea of permanent endowment. We cannot feel sure, as we have previously said,[1] that the mere relief of the hospitals from debt would afford any security against the same condition recurring in a few years—and, therefore, we think that a permanent endowment in some form or other is the end to aim at. That there are difficulties in the way of carrying out this scheme, and those no small ones, we well know, but surely the overcoming of them is not impossible, and would be a note of special importance in a year which it is hoped will be so remarkable in many ways.

THE COMMENDATORE LUIGI PAGLIANI, who is described by our Rome correspondent as the highest hygienic authority in Italy, has recently delivered, in the Turin University, where he holds the chair of Public Health, an opportune discourse on the Pestis Bubonica considered from an etiological and prophylactic view-point. Having glanced at its history, particularly at its memorable visitation of Byzantium in the sixth century, as described by PROCOPIUS, Professor PAGLIANI said that it reached its height in Europe during the fourteenth century. In the sixteenth century it registered a decline, which it has steadily maintained, till in the first half of the century now closing it quite disappeared from Europe, from Turkey, and from Egypt herself. An attempted invasion on the Russian frontier at Weltyanka in 1878–79 was followed by a more successful "reconnaisance en force" in Mesopotamia, Syria, and Persia, where it remained endemic. Thence it diffused itself to Turkestan, to Upper India, to

[1] THE LANCET, Jan. 2nd, 1897.

Hosted by Google

Southern China, from which it returned reinforced to Hindustan, especially Bombay. The intimate, uninterrupted relations of that port with the great European maritime cities inspired a note of alarm which was first responded to by the sanitary council of Alexandria, whose initiative was followed, particularly in the Mediterranean, by vigorous measures of precaution. Two conditions, said Professor PAGLIANI, render our times less panic-stricken in face of the enemy. First, our public health is more vigilantly supervised; and second, we know the micro-organism which is the efficient cause of the bubonic infection. Under the former there is infinitely less likelihood of that micro-organism acquiring a foothold; under the latter we have knowledge of the means of neutralising or disarming it. Recounting the well-known discovery of KITASATO and YERSIN, by which the bacillus bubonicus is recognisable, he further described the later studies of ZETTNOV and KOCH by which our familiarity with its nature and habits has been extended. For prophylaxis it is especially important to know that we have to deal with a "bacillus asporigenus" which dies after four days during which it is kept at a dry heat, or at the temperature of 80° C. for half an hour, or at that of 100° C. for a few minutes. Its resisting power to chemical disinfectants is feeble, succumbing shortly in a 1 per cent. solution of carbolic acid or of lime water. On the other hand, it develops easily in many culture media at the ordinary temperature (from 18° to 22° C.), having been found in the soil or in the dust of houses where those ill from it, or who have died from it, have been lodged. It affects not only man but even animals who share his dwelling-place. Rats, for instance, fall easy victims to it, and, as a rule, die in large numbers at the beginning, or in the course, of the epidemic. Not so well ascertained is the susceptibility to it of pigs and oxen. As to the latter, LOWSON'S direct and very accurate experiments would give a negative result. In the light of these the highly virulent bacillus found by KITASATO in dead cattle during an epidemic of "human" pestis would rather be the bacillus of the "bovine" order of the disease. The channels by which the infective agent finds entrance are very slight lesions of continuity in the skin and mucous membrane, from which it passes into the glands connected with the lymphatics nearest the point at which the agent had penetrated. Thus it is that AOYAMA explains the fact that the Chinese, who walk barefoot, are generally attacked by it at the inguinal glands, and the Japanese, who wear shoes, are almost exclusively affected at the armpits. For the same reason workers in oleaginous materials, and who live hygienically clean, are proof against it. The medical attendants and their assistants are not infected by their patients. AOYAMA was an exception, as was also his assistant; but they became infected while performing a necropsy. The incubation of the malady lasts from two to seven days. As a rule it develops most rapidly, presenting, together with tumefaction of the lymphatic glands, the symptoms usually met with in the graver infective fevers. The whole lymphatic system, especially at the groins, the internal viscera, and the blood are invaded by the typical bacillus and also by germs common to purulent infections. Death is the most frequent issue, supervening in from 70 to 90 per cent. of cases. Often it occurs in the very first days of the attack—rarely later than the eighth day of the malady. As for prophylaxis Professor PAGLIANI holds that the greatest circumspection must be practised in the admission into harbour, or into free intercourse, of craft which have had cases of plague on board. Such ships should in every case be subjected to the most stringent disinfection. Goods not of personal or domestic use are less to be feared from the prophylactic point of view. Skins arriving already treated with arsenic, or lime, or saltpetre, and in the dry state, may be held innocuous and, *pro tanto*, exempt from the disinfector's care.

WE have again and again raised a protest against the present system of teaching and examining as being responsible for the marked decline in the amount of time given by the medical student in late years to the practical work of the professional curriculum. The period of study has been lengthened, but we see no evidence of an increased attention to those practical subjects which form the bedrock on which his subsequent daily work must be founded. Scientific subjects are allowed to increase daily and to encroach more and more on the time which should be spent in the dissecting-room, the laboratories, and the wards and out-patient rooms of the hospital. The first year is now devoted to chemistry, physics and biology, the examinations in these subjects are specially arranged to favour cramming and text-book knowledge, and the judgment of the examiners as to the proficiency of the students in these sciences is often erroneous because the tests of the practical work are wholly inadequate. In many cases an up-to-date superficial knowledge enables one candidate to pass when another fails although he has tried seriously to obtain a practical and useful insight into these preliminary subjects. The examinations on the theoretical side are either too severe or are too superficial, whilst the practical examination is so scanty that the teacher inevitably recommends the getting up of a given text-book (the newer the better) instead of advising honest and thorough practical work in the laboratory. In biology the morphological aspect takes precedence, and the structural details of the animals which the student can observe for himself disappear into the background.

Passing on to the next period of the student's career, every anatomical teacher who is familiar with the daily work of our profession deplores the decadence in practical anatomy which is now so marked. We do not hesitate to say that the number of medical students who now thoroughly dissect the human body, so as to show and to see the structures clearly, is much less than it was fifteen or twenty years ago and is gradually dwindling to a minimum. Yet it is from these students that the future surgeon must come. The student is no longer to study anatomy in its application to the practice of medicine, surgery, and midwifery, but he is to be taught this eminently practical science "from a morphological standpoint, and as a member of the great animal series." His science is everything; his practical investigation for his after career is relegated to quite a subsidiary place. So in physiology the time that was formerly allotted to the

Hosted by Google

elucidation of the functions of the human body, to the proper methods of preparing histological sections of the organs, and to the broad facts in the chemistry of the secretions, is now mainly occupied with minute details of physical and chemical experimental physiology, so that the student cannot see the forest because of the immense number of the trees. Such a course, again, may be advantageous to a pure physiologist, but it is entirely outside the training necessary for a medical practitioner. But as the examiners are specialists in their own branches of science or in some sub-division of them, so must the student be, and he is, crammed with innumerable details to the great deterioration of his reasoning faculties.

The later subject which will require all his time and attention are the clinical ones—medicine, surgery, and midwifery—and here, too, the text-book knowledge has been permitted to predominate over a real acquaintance with the practical recognition and treatment of disease. Then, again, the examination system at present adopted by most qualifying boards is at fault. Undue limitation of time and the exclusion of acute cases are fatal to a just examination, however conscientious the examiner may be. The methods of the examination room are often quite different from those employed in actual practice. We are glad to see that practical teachers like Mr. MITCHELL BANKS, Mr. PRIDGIN TEALE, Dr. STRUTHERS, and others are with us in this protest, and Mr. THOMAS COOKE has done good service in bringing the subject prominently before the profession in his pamphlet on "Specialism in Teaching and Examining." We do not agree with all his deductions, but the subject is one that requires very thoughtful consideration with a view to a reform of the present system both of teaching and of examining.

Annotations.

"Ne quid nimis."

BACTERIOLOGY IN THE CURRICULUM AND EXAMINATIONS.

IT may be remembered that last autumn Dr. Pavy moved the Royal College of Physicians of London to inquire into the question of the desirability of including the subject of bacteriology in the course of study and examinations required for the Licence of the College. Fears were freely expressed at the time whether it would be possible to introduce it without adding unduly to the burden of the student or imperilling the position of subjects of more immediately practical value. On the other hand, no one could fail to recognise that the study of bacteriology and its fruits was becoming essential to the proper understanding of many pathological and etiological problems, whilst it had also been gaining a position in clinical diagnosis and therapeutics. In point of fact, this young and vigorous department of science had already established its claim to a position in the curriculum of the medical student. The committee which was appointed to consider and report upon the question consisted of Dr. Pavy (chairman), Dr. Church, Sir Dyce Duckworth, Dr. Ord, Dr. Poore, and Dr. Washbourn (secretary). Their report was made to the last Comitia, and had been prepared after careful inquiry into the method and extent of instruction given in bacteriology in Continental as well as British schools. Their recommendations do not involve any very extensive departure from the rules at present in force. The subject being considered a branch of pathology they did not deem it necessary to make any special mention of it in the examination schedules; whilst with regard to the curriculum the specifying of other branches of instruction in the syllabus suggested the propriety of naming bacteriology as part of the course in pathology required of all students preparing for the college examinations. We think that these recommendations are wise and prudent. They admit the necessity of the medical practitioner being instructed in the leading facts and principles of bacteriology, and they show the student that the subject is one upon which he is liable to be questioned in the examination room. But the position assigned to the subject is one which is subordinate to the general subject of pathology rather than one of splendid isolation, requiring absorption of a large amount of time in its study and a distinct set of expert examiners. Nor from what is the prevalent custom of pathological teaching in schools and textbooks does this view of the position of bacteriology appear novel. The new revised regulations simply preclude the subject being ignored.

THE PLAGUE AT MARSEILLES IN 1720.

M. DELUNS-MONTAUD, formerly Minister and Member of the French National Assembly, has found among his family papers the draft of a report on the great plague which devastated Marseilles in the years 1720 and 1721. The manuscript is damaged and the name of its author effaced, but, judging from its contents, it seems to have been written by one of the three medical delegates of the Montpellier Faculty who were appointed to investigate the cause and development of the epidemic. As two of these delegates—Dr. Vernier and Dr. Chicoyneau—did not believe that the plague was contagious, the writer of the manuscript in question was probably the third delegate, Dr. Deidier, for he held the contrary opinion, a view confirmed in certain passages of the document. The Paris *Temps* publishes this interesting manuscript, from which we extract the more important passages. The author commences by relating that, at the time he was writing, some 30,000 persons had died from the plague in the town of Marseilles, including thirty monks and nuns and twenty surgeons, with a due proportion of their assistants, and "five or six doctors who died miserably without honour to themselves. I say miserably and without doing themselves honour because, seeing the disorder which prevails in the town, the want of food supplies, the general despair, the abandonment of the sick, it was not possible for them to fulfil their functions and efficaciously help the sufferers." The disease is described as "refined plague" (*peste raffinée*), characterised by charbon, bubos, and purple patches, and by its rapidly fatal results. The patients died in from one to three days, and sometimes suddenly without any premonitory symptoms. The first symptoms were pains in the head, troubled sight, a dazed condition, and a trembling voice. Then a cadaverous appearance, cold at the extremities, unequal pulse, nausea, collapse, delirium, and finally convulsions or hæmorrhage, followed promptly by death. In some cases the pulse was rapid and the beat evenly distributed. Among these several recovered in consequence, we are told, of repeated bleeding, emetics, laxatives, diuretics, and some cordials. If the malady lasted for more than five or six days there was some chance of escape, but such cases were rare exceptions; by far the greater number of patients died. The post-mortem examinations are described as having shown gangrenous inflammation of the stomach, chest, and brain. With regard to the cause of the plague, "every one is agreed that the evil only commenced after the arrival of a ship from India

Hosted by Google

on which five or six sailors had died from the same sort of illness during the journey. Some merchandise from this ship was secretly, and without the exercise of any precaution, transported to one of the streets where four people lived and which was the first to be infected. The inhabitants of this street, having traffic with other quarters, spread the contagion. The porters who first removed the merchandise all died suddenly in the infirmary, and what proves that it is a veritable plague is the destruction of entire families when one member is attacked; father, mother, children, servants, all share the same fate, and, if one among them took refuge in another house he carried with him the same disease which there caused the same ravages. This has led to the abandonment of the sick, who, being deprived of all help, have perished, for they had no broth, or bread, or water to help them in their distress. Even the corpses remained several days in the houses and the streets without its being possible to find any one to bury them, since all those who buried the dead also died. The panic-stricken magistrates have neither the time nor the presence of mind to give suitable directions. They have lost all authority and are no longer obeyed. Indeed, the police commissioners and the public health functionaries of the districts have fled away. You will see by these facts what must be the melancholy condition of the town. We shall deem ourselves fortunate if we have escaped the contagion. At least the town of Aix is exempt and will protect itself. This exemption, I hope, will be the result of the good order prevailing at Aix, for I am persuaded that by these means only, and above all by sobriety, good food, confidence, moderate exercise, is it possible to shelter oneself against the contagion." These words seem to have been written after their author had left Marseilles and while he was undergoing quarantine in the neighbourhood of Aix, which is the political capital of Provence, while Marseilles is its commercial capital. Altogether some 60,000 persons died, and the mortality would have been much greater had it not been for the heroism of the Bishop Belzunce, who did his utmost to combat the general despair and who organised a system of relief and such nursing as was possible.

PSYCHICAL RESEARCH AND THE ROENTGEN AND OTHER X RAYS.

MR. WILLIAM CROOKES, F.R.S., whose tubes have been a necessary medium in the discovery of the Roentgen rays, delivered his presidential address to the Society for Psychical Research on Jan. 29th. Although the society has been in existence for fifteen years and "has done some excellent work" and the science with which it deals is "still in a purely nascent stage," yet he predicted that "psychical science as pursued by the society is the embryo of something which in time may dominate the whole world of thought." Over twenty years ago Mr. Crookes made some researches which attracted considerable attention among those investigating psychical problems, and he assured the society that he had still his old-standing interest in these just as when he had his first glimpse of some important laws of matter and energy which a large number of scientific men still do not recognise. Speaking of the newly-discovered Roentgen rays he said: "We are introduced to an order of vibrations of extremest minuteness as compared with the most minute waves with which we had hitherto been acquainted." "It has been demonstrated," he continued, "that these x rays as generated in the vacuum tube are not homogeneous, but consist of bundles of different wave-lengths analogous to what would be difference of colour could we see them as light, some passing easily through flesh but partially arrested by bone, while others pass with varying facility through bone but less easily through flesh." He considered it possible that other x rays exist in which vibrations are of a more extreme minuteness, as there is no reason to suppose that we have reached in the Roentgen rays the limit of frequency, and that some of those unknown rays may supply the key to much that is now obscure in psychical phenomena, as in telepathy—"the transmission of thought and images directly from one mind to another without the agency of the recognised organs of sense." By adopting such a hypothesis "no physical laws are violated, neither is it necessary to invoke what is commonly called the supernatural." Objections, he allowed, may be taken to this hypothesis, but in making objections to, or in answering these, it must be remembered that we cannot "express life in terms of heat or of motion" and other purely physical conditions. Doubtless "molecular movements strictly obey the law of the conservation of energy, but what is called *law* is simply an expression of the direction along which a form of energy acts, not the form of energy itself." He continued: "We may explain molecular and molar motions and discover all the physical laws of motion, but we shall be as far as ever from the solution of the vastly more important question as to what form of will and intellect is behind the motions of molecules, guiding and constraining them in definite directions along pre-determined paths."

THE EPIDEMIOLOGICAL SOCIETY AND THE ROYAL COMMISSION ON VACCINATION.

AT the last council meeting of the Epidemiological Society, held on Jan. 15th, 1897, it was resolved to submit the following resolution, in reference to the recent report of the Royal Commission on Vaccination, to the next ordinary meeting for adoption:—"That this society, while noting with satisfaction the pronouncement of the Royal Commission as to the value of primary vaccination, and the necessity for maintaining it, regret that, although the report also brings forward conclusive evidence as to the value of re-vaccination, the Commissioners have not seen their way to recommend legislation which would place it on the same basis as primary vaccination." The Epidemiological Society in former years took an active part in the question of vaccination, and its carefully prepared report on the subject was of material assistance to the Legislature in framing the Vaccination Acts. Doubtless the increasing proof of the need of re-vaccination as a protective which the experience of later times has brought may have weighed with its Council in submitting the above resolution to the society. If it does nothing more it will, at any rate, show that those who have the best opportunities of judging the question are persuaded of the importance to the community of securing a system of re-vaccination comparable to that to which Germany owes her immunity from small-pox.

THE NUMBERS OF THE PROFESSION.

BY the kindness of the Assistant Registrar of the General Medical Council we have been favoured with the statistics of the profession as they will appear in the forthcoming issue of the Medical Register for 1897. They scarcely mitigate the sense of undue increase in the numbers of our ranks which arose from a perusal of the data supplied in the Medical Directory. The number of practitioners holding British qualifications in the United Kingdom and out of it in the Medical Directory for 1897 is 34,284, an increase of 964 over that in the same work for 1896. According to the statistics of the forthcoming Register the number of registered practitioners with British qualifications is 34,478. The number in the Register of last year is 33,601, or an increase of 877. The particulars of this huge total are as follows:—New registrations: England, 780; Scotland, 477; Ireland, 128; restorations to the register, 52; total, 1437. From this must be deducted for removals; by death, 532;

Hosted by Google

under Section 14, 25; under penal section, 3; total, 560. The actual number on the Register is affected by the removals chiefly under Section 14, which is a mere postal matter, and subject to variation according to circumstances or the action of the Council. Though the number on the Register grows from the excess of new registrations over the number of deaths it does not appear that the number of new registrations is increasing. For the last three years the numbers are, respectively, 1579, 1426, and 1385.

A FEW CHOICE "LOTS."

THE difficulties experienced by a country printer in setting up technical medical terms are amusingly illustrated in a document which has recently come into our possession. It is headed, "The Late Dr. L. Essay's [this is not, of course, the correct name, but it will serve our present purpose] Sale of Household Goods. Copy from Catalogue," and was doubtless sent round to the medical practitioners of the neighbourhood to attract them to the sale. We hope it did, for such an opportunity may not occur again! The following are some of the "lots":—741, a Haryngscope in case; 746, two silver cathetus in case; 747, Wet capping instrument in case; 748, Shphygniograyh (Mareys); 755, Syringe (Waginal); 759, Trocars and Camicula in case; 766, Midwifery Bags, Forceps, long and Rigot Case inside; 774 (by way of variation), Frocar and Camicula. 775 is delicious—viz., Minnim Measles in Box; as is also 781, Hosh (double) (can this be a truss?); 785, Hypodermis Case; 804, Box of Cathartics; 806, Porcelain Pressary; 822, Tensillotome; 827, Gynelological Instruments, &c., in paste-board box. Amongst books we find—839, Practical Orthop Acdiess, by Reeves; and 854, Human Orthology (what this science may be is a little difficult to guess). The last "lots" that we need stop to note in this "strange, eventful" catalogue are—859, "Enteric Fever," and 860, "Spinal Disease and Curvature." We wonder what their purchasers will do with them! If, indeed, they could happily contrive to keep securely under their own control such dire afflictions of mankind their names would deserve to go down to posterity coupled with those of Edward Jenner, Pasteur, and Lister. We will only add that we grieve to observe that "Dr. L. Essay" was the possessor of an "Ammoniaphorl (Harness)."

REMOVAL OF FOREIGN BODIES FROM THE STOMACH.

IN the *Deutsche Medicinische Wochenschrift*, No. 4, 1897, is an interesting paper by Dr. Fricker of Odessa describing an extraordinary case in which several foreign bodies were removed from the stomach of a woman and giving also a *résumé* of the literature of such cases and a table containing abstracts of 27 cases in which an operation had been performed for the removal of objects which had been swallowed. The case under Dr. Fricker's own care is certainly worth recording. The patient was a woman, aged thirty-two years. There was no history of insanity in the family. Between the ages of fourteen and fifteen years she was subject to "hysterical attacks." She married when seventeen years old and had eight children in quick succession (twins once) and two miscarriages. Eighteen months before coming under notice she had been much depressed by the loss of a child, and three months before a second child had died, and since that time she had been very melancholic, and several times attempted suicide by swallowing petroleum and carbolic acid, and then solid substances such as needles, nails, and small buttons. At first the patient made no complaint after performing these exploits, but subsequently experienced much abdominal pain. Various forms of treatment had been tried for the general condition, such as baths, electricity, &c., but without avail. A tender swelling appeared in the left side of the abdomen and an operation was decided upon. An abscess was found in the region of the swelling, and the stomach had evidently been perforated, but the site of perforation could not be discovered. With all due precautions the stomach was opened and the following bodies removed: a key (7·5 cm. long and weighing 21·38 grammes), a silver teaspoon (15·5 cm. long and weighing 25·15 grammes), a metal teaspoon (weighing 36·5 grammes), a fork (20·5 cm. long and weighing 84·75 grammes), two wire tacks, two hair-pins, two pieces of glass, one window hook, one steel pen, nine sewing needles, one piece of black-lead, one shoe-button, one grape-stone, two small lumps of tin, and one crochet-hook, the whole weighing 261·85 grammes. (A very good illustration of all these objects accompanies the paper.) The stomach was washed out with sterilised salt solution and the wound closed. The patient made a good recovery. Dr. Fricker gives a second table showing the statistics of such operations. I.—Before the days of antiseptics, 19 cases; 15 recovered and 4 died. An early operation was performed on 1 patient who died. Operation was delayed in 10 cases, and of these 9 recovered and 1 died; the time of operation was not recorded in 8 cases, and of these 7 recovered and 1 died. II.—Antiseptics were used in 35 cases; 29 recovered and 6 died. An operation was performed soon after the foreign bodies were swallowed in 10 cases; 8 recovered and 2 died. The operation was postponed in 17 cases; 15 recovered and 2 died. The time of operation was not known in 8 cases; 6 recovered and 2 died. To sum up these cases, then, an operation was performed in 54 cases, of which 44 (81·4 per cent.) recovered and 10 (18·6 per cent.) died. The result of such an operation can, therefore, only be regarded favourably.

FOOD ADULTERATION: PAST AND PRESENT.

IN a paper read before the Medical Society of Charing-cross Hospital on Jan. 13th on the Adulteration of Food Mr. P. A. E. Richards, F.I.C., public analyst of the parish of St. Martin-in-the-Fields, referring to the history of this subject, stated that although reference is made to it in writings dating back to the ancient Greeks it was not until the beginning of the present century that adulteration reached that degree of perfection, a regards precautions taken to avoid detection, that almost entitled it to be termed a fine art. Some of the methods of punishment in vogue in the old days might perhaps be revived at the present time with advantage and profit, such, for example, as that of the pillory and tumbril for sophisticating wines; in the reign of Edward I. a baker, on conviction for selling short weight, was ordered to be drawn upon a hurdle from the Guildhall to his own house "through the great streets where there be most people assembled and through the great streets *that are most dirty*." Satisfactory legislative control over the purity of the food supply of the country was, however, not seriously considered (with the exception of the Act, very limited in character, passed in 1836) until THE LANCET, in the year 1851, under the editorship of the late Mr. Thomas Wakley, started its famous "Analytical Sanitary Commission." One of the results of this inquiry was the appointment of a Parliamentary Committee, followed by the passing of the Sale of Food and Drugs Act, 1875, and its Amendment Act, 1879, which are the statutes at present in force. Although much time and trouble had been devoted to rendering these Acts as satisfactory as possible, still, as was pointed out, various improvements might be made. Mr. Richards mentioned, among other instances, the case of coffee mixed with chicory. Although the latter substance was frequently present to an infinitely greater extent than

Hosted by Google

the former, the label usually showed coffee in prominent capitals, whilst the important statement "mixed with chicory" was hidden away in an unobtrusive position in the bulk of the lettering. These and similar defects in the Act it was hoped would be remedied by the recommendations recently made by the Select Committee on Food Adulteration. An interesting demonstration with the microscope, illustrating some methods of modern adulteration, added considerably to the interest of the paper.

NURSES AND THE COMMEMORATION FUND.

THE Duke of Westminster writes again to the *Times* on behalf of the Queen's Jubilee Nurses Commemoration Fund, and there is no doubt that Her Majesty is deeply interested in the problem of supplying nurses to the poor. At present, owing to the exaggerated notions of the training necessary for nurses, they are a luxury of the rich or the well-to-do classes, and the poor and, indeed, the lower section of the middle classes have to do without them as best they can. But this is only one part of the problem of meeting the care of the sick poor and must yield in importance to the hospital part of it. And there are indications that Her Majesty would be pleased with any form of commemoration which made the hospital provision for the really necessitous poor more adequate than it is. It remains to be seen whether the hospitals have friends as energetic and persuasive as the Duke of Westminster.

THE SERUM DIAGNOSIS OF TYPHOID FEVER.

THE December number of the *Canadian Practitioner* contains an interesting paper by Dr. J. J. Mackenzie, bacteriologist to the Provincial Board of Health, on the Recent Practical Application of the Serum Reaction of Pfeiffer in the Diagnosis of Typhoid Fever. The writer gives a short history of the reaction and then describes the method he has found most satisfactory. This method was introduced by Dr. Wyatt Johnston of Montreal. A drop of blood from a suspected case of typhoid fever is allowed to dry upon a slip of paper and then later, in the laboratory, the drop is moistened with sterile water and a portion of it mixed with a drop of fresh bouillon culture of typhoid bacilli. This is watched under the microscope, and if the case is one of typhoid fever in the course of from half an hour to an hour agglutination of the bacilli occurs. Dr. Mackenzie finds that after mixing the culture and the watery extract of the blood of a typhoid fever patient as a rule no change is observed for a few minutes, the bacilli moving rapidly backwards and forwards through the field with their characteristic motion. Then it is noticed that individuals stick together in pairs or in threes, moving clumsily, and in a short time others join the clumps, the movement becoming always slower, until finally all the bacilli are tangled together in large clumps containing ten or more individuals and all movements stop. The reaction takes longer in some cases than in others. In one case it was complete before the preparation could be placed under the microscope—i.e., in about two minutes. In the majority of cases it takes thirty minutes. Dr. Mackenzie states it as his experience that if there is no evidence of reaction within an hour there is not much chance of its appearing, but it is well to observe the slides for twenty-four hours. In order to be sure of accurate results a very motile culture must be used—i.e., a fresh one—and it is well to have it so dilute that not more than, say, from fifty to a hundred bacilli appear in the field. Dr. Mackenzie has tried the reaction in eighty-two cases, in some of them upon several samples of blood taken at different times. Sixty-one of these were cases of typhoid fever, or subsequently proved to be typhoid fever, and in fifty-seven of these he got a positive reaction; in four he obtained no reaction. In twenty-one which were not cases of typhoid fever, or subsequently proved not to be typhoid fever, a negative reaction resulted in all; there were, amongst other non-typhoid cases, tuberculosis, acute dilatation of the heart, articular rheumatism, septicæmia, and blood from healthy individuals. A number of cases of tuberculosis were tested, including two cases of meningeal tuberculosis, with negative results in each case.

THE LANCET RELIEF FUND.

UNDER the heading "THE LANCET as an Agency of Charity" the *New York Medical Journal* of Jan. 23rd, 1897, contains in the form of a leading article an appreciative notice of our Relief Fund. Curiously enough our contemporary seems to look upon the Fund as only just established, but, as our readers are aware, the Fund was started in 1889, and on Jan. 9th we published the eighth annual report in our columns. Our contemporary concludes by observing:—

"It is easy to see that by means of this fund numerous instances of real distress among deserving persons may be relieved, and the regulations are such, we should say, that it would be difficult for the almoners to be imposed upon. We look upon the undertaking as an outgrowth of pure philanthropy and as exceedingly creditable to the proprietors of THE LANCET, but we hope that not many of our British brethren will find themselves in such straits as to have to resort to the Fund."

From the final remark it would seem that the services of medical practitioners in America are more liberally requited than is the case here. The *New York Medical Journal* may be interested to know that during the eight years our Fund has been in existence 355 applications have been made by medical men or their widows, and in some of these cases we are glad to know that the assistance afforded has been the means of enabling the recipients to make a fresh and fair start in life.

IMPORTANT DECISION AGAINST A PROPERTY OWNER.

A CASE of great importance, especially as it bears upon the responsibilities of owners of house-property, has just been decided by Mr. Justice Mathews and a jury, the plaintiff being a widow living at Sutton, Surrey. This woman, the wife of a gardener, sued to recover £1000 as damages for his death. He lived in a cottage at a short distance from which, and on a higher level, were a row of similar tenements belonging to one of the defendants, a Croydon builder named James Manser. The cottages were drained by means of two cesspools, the overflow going into a soakaway, from which it percolated through the soil. The consequent nuisance became so bad that the deceased and his wife had to keep their doors and windows closed, and the man complained to the urban council first (it was alleged) in February last year and subsequently. In May the council's surveyor—the urban district council was made a co-defendant body—took steps to ensure an abatement of the nuisance. For various reasons, however, the evil was not remedied by Manser and the houses were unconnected with the sewers until July 4th. Meanwhile on June 25th the gardener was taken seriously ill, Mr. F. D. Atkins diagnosing septic pneumonia. A nurse who took charge of the case had to leave within a week, being herself taken ill, and the man died on July 19th. Mr. Atkins most properly declined to give a certificate on the ground that the case ought to be inquired into, and the jury at the coroner's inquest found that the death was due to blood-poisoning caused by bad smells from the overflowing cesspools. This was the case for the plaintiff. It being shown that no stoppage in the drain had occurred—the ground apparently of the action against the urban council—that part of the claim was withdrawn, the judge suggesting in the

Hosted by Google

circumstances that the council should not press for costs. Manser declared that he had sent the plans for the connexions on May 20th, but a letter from him containing the words, "Herewith I enclose plan," and dated June 26th was put in, and he confessed he "had made a mistake and must abide by it." The jury found for the plaintiff, with damages of £140 for the widow and £40 for each of the children—£300 in all.

ACCIDENTS AND INSURANCE COMPANIES.

IF we may judge from a decision recently given in an American Court of Law[1] it behoves insurance companies to define very clearly to their own official intelligence and to the minds of their policy-holders the scope of the term accident. In the case in question death had followed blood-poisoning which originated in an abrasion due to wearing a tight shoe. A question of responsibility arising was decided by the local bench in favour of the representatives of the deceased, the cause of his death being treated as a pure accident for which he was not accountable. Such a result must surprise others besides our transatlantic contemporary. Whatever meaning the word accident may convey to the minds of insured persons or their friends it cannot surely in good English, or even in "American," be so stretched as to indicate more than a given injury and its natural consequences. A tight boot does not come within the number of arrangements necessary or usual in ordinary life. On the contrary, it is a fault in itself, and should therefore tend rather to disqualify claims founded on its use. This, however, is possibly in some instances accidental. The legal significance of an abrasion caused by it may be in like manner somewhat doubtful. But blood-poisoning has no natural connexion with such an abrasion, and there seems to be no reasonable doubt that the fatal disease which followed in the case above related was an evidence of neglect in the after-care of the wound.

A FAVUS-LIKE ERUPTION OF THE ORAL MUCOUS MEMBRANE CAUSED BY THE ASPERGILLUS NIGER.

THE aspergillus niger is well known to aural surgeons as the cause of a somewhat rare disease of the external meatus. A case, recorded by Winfield,[2] in which the fungus established itself in the mouth, is quite unique. The patient, a healthy woman, aged twenty-seven years, noticed a "small ulcer" on the roof of the mouth in the middle line, half-way between the incisors and soft palate. It produced no discomfort except when pressed on by hard food. It gradually increased in size and satellites also formed. When first seen there was an œdematous and lumpy patch extending from the incisors to within a quarter of an inch of the soft palate to the left of the middle line. There were also two round, cup-shaped elevations on the soft palate, symmetrically placed on either side of the middle line, and one of irregular outline behind the left incisor and canine teeth. The patches were more or less covered with a dirty yellow deposit, firmly attached to the swollen tissue underneath. Removal produced slight hæmorrhage. The colour of a recent deposit suggested the sulphur-coloured scutula of favus, but that of older date was more of a greyish-brown. The clinical picture was unlike anything seen before. Favus and tuberculosis suggested themselves. The microscope showed with a low power a fungus which differed from the achorion. The mycelium was composed of delicate fibres, which showed no tendency to fission, and which bore hyphæ. Scattered over the field were a number of fruit receptacles and a few loose spores. Agar tubes were inoculated. At the end of twelve hours they showed on the surface small white dots. These rapidly grew until the whole surface was covered with a yellowish-white mould, which in about thirty-six hours changed to greyish-brown. A mild caustic, composed of equal parts of resorcin, antipyrin, and creosote, was applied to the mouth. This checked the growth as long as the weather remained cold. But on the approach of spring it began to grow again and invaded the gums. A 25 per cent. peroxide of hydrogen solution was then tried. Improvement was at once noticed, and the patient recovered in seven weeks.

COLOUR PHOTOGRAPHY.

PHOTOGRAPHY in natural colours appears at last to have been achieved, and if this be so an advance equal in importance to that brought about by the x rays has been made. The process is at present a secret one, and will doubtless remain so until the necessary steps are taken to protect the rights of the inventor. From a purely scientific point of view it is regrettable that such a course has been decided upon, but in these utilitarian days there are few, we imagine, who would be justified in finding fault with the inventor on this account. The process, which has been demonstrated in the laboratory of King's College in the presence of such authorities as Professor Millar Thomson, Mr. Herbert Jackson, Captain Abney, and Sir Henry Trueman Wood, consists in taking a negative in the ordinary way on a gelatin plate which has been treated with a solution of certain salts the nature of which is a secret. The negative is developed in the ordinary way and differs in appearance but little from an ordinary negative. The positive produced from this looks like an ordinary transparency with no sign of colour. It is then immersed after the manner of intensifying an ordinary negative by mercury solution, in three coloured solutions, blue, green, and red, when the tones appear to possess a selective action, selecting just that colour and tint which characterise the parts of the original subject. The results, it is stated, are exceedingly beautiful and artistic and surpass the achievements of hand work. This announcement will, we are sure, be received with the greatest interest by our readers, since the new method should lend most valuable assistance to the faithful portrayal of the many conditions of the human subject which occur in medical and surgical practice.

THE RETIREMENT OF DR. CHEPMELL.

WE are sorry to learn that an old member of our foreign staff, Dr. Dobrée Chepmell, has been compelled by failing eyesight to retire from practice in London and to pass the winter in Bournemouth. Dr. Chepmell received his early medical education at King's College when that school flourished under the auspices of Todd, Budd, Fergusson, Partridge, Bowman, and Simon. In 1850 he obtained a travelling appointment, residing for eight or nine years with the late Lord Holland in France and Italy, and made himself familiar with the languages of both countries. Towards the end of the fifties he married and settled in Paris, becoming "Our Own Correspondent." This post he occupied until the duties of a large and increasing practice left no time for literary work. At the outbreak of the Franco-Prussian war Dr. Chepmell, with most of the English residents in Paris, migrated to London and commenced work as a consulting physician enjoying the confidence and friendship of many of the distinguished exiles and specially of the Empress Eugenie. During last autumn, whilst on his holiday in Guernsey, his native place, an attack of acute glaucoma in the right eye made its enucleation necessary in order to save the other. The operation was quite successful, and the result has been an improvement in the vision of the remaining eye. We sympathise most fully with Dr. Chepmell and deplore the cause of his enforced

Hosted by Google

retirement, but at the same time are inclined to think that in such an "innings" as twenty years of a full-swing practice in Paris and twenty-five in London there are some grounds for congratulation.

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY, LIMITED.

THE annual meeting of this society will be held on Tuesday, Feb. 16th, at 12, New-court, Carey-street, Lincoln's Inn-fields, at 4 P.M. It is with satisfaction we note in the annual report to be submitted on that occasion by the council that the past year has been a prosperous one for the society, which now enters on its fifth year with excellent prospects, and that the growth of the society in numbers has of late increased at a rapid pace. Upwards of eighty cases have been dealt with in the past year. The income of the society has amounted to £647 8*s.* 6*d.*, whilst the expenditure has been £392 6*s.* 11*d.*, thus leaving a surplus for the year of £255 1*s.* 7*d.* This last amount, together with the balance of £126 18*s.* 9*d.* carried over from 1895, gives the total amount of cash standing to the credit of the society's general account and reserve fund account on Dec. 31st, 1896. All debts incurred by the society during the year having been paid by Dec. 31st the new year was commenced without liabilities of any kind. A reserve fund has now been formed with Sir William Broadbent and Mr. Pickering Pick as trustees. Dr. Heron is the treasurer of the society and Dr. Hugh Woods and Mr. A. G. R. Foulerton the general and financial secretaries respectively.

INJURIOUS FUR COLLARETTES.

SEVERAL cases have occurred lately in which a rash upon the neck seems to have been produced by the wearing of sable collarettes, and quite recently we published two such cases in THE LANCET of Dec. 12th, 1896. We have met with another case which has afforded us the opportunity of submitting to examination a fur that had apparently caused an eruption and another which had been worn (without any objectionable results ensuing) by the same individual. It is worthy of note that the sables in question appeared to be of Canadian origin. The acute dermatitis following upon the wearing of a sable collarette has been very generally attributed to the presence of arsenic or some other irritant which it is suggested may have been used in the skin of the animal as a preservative. We, therefore, very carefully tested a sable skin which had produced an eruption, but we failed to find any trace of arsenic, mercury, or other chemical irritant. We are more inclined to think, therefore, that the irritation was due to a mechanical cause. It is well known that in many sensitive skins a rash is sometimes produced by mere contact with substances that have brittle and minute points. Glass-wool and asbestos, for example, cannot always be handled with impunity, a rash on the hand extending to the arm frequently following contact with these materials, although in themselves they may be quite soft and even suitable for the stuffing of seats and cushions. On examining the hairs of the fur of an old animal, the collarette made from which had apparently produced an eruption, they were found to consist of somewhat thick and rigid rods with sharp points at the tip, whereas the hairs of the fur of a younger animal, the collarette made from which proved to be free from objection, were found to be of a much finer character throughout and of a uniform thickness from the tip to the root. The hair of the older fur proved to be more rigid and less yielding than the hair of the younger fur, and therefore is more likely to prick the skin, especially as although the body of the hair is thicker the tip is a fine point. A simple experiment sufficed to afford distinct evidence of the validity of this view. It was found that when a fur that had been known to produce irritation was gently pressed upon a slab of soft grease the hairs penetrated into the fat, while the hairs of a younger fur did not penetrate it, but were bent round in a curve. It would therefore seem that in choosing a fur the one derived from a comparatively young animal should be preferred, and persons with sensitive skins or exhibiting an idiosyncrasy would do well to avoid the fur of an old animal and obtain some guarantee of the age of the skin purchased, although by making this selection the more handsome furs would probably have to be rejected.

THE PREVENTION OF OPHTHALMIA NEONATORUM.

THE *Maryland Medical Journal* states that last November Dr. John S. Fulton, secretary of the State Board of Health, prosecuted Mrs. Liersman, a registered midwife, for violation of the law enacted by the Maryland Legislature in 1894, "To Prevent Blindness in Infants." This was the first trial under the statute in question. The accused acknowledged having received from the Health Office of Baltimore a copy of the law and also a circular letter giving directions concerning the care of infants' eyes. A fine of 25 dollars and costs was imposed. The law is as follows: "An Act to prevent Blindness in Infants. Section 1.—Be it enacted by the General Assembly of Maryland: That if at any time within two weeks after the birth of any infant one or both of its eyes, or eyelids, are reddened, inflamed, swollen, or discharging pus, the midwife, nurse, or person other than a legally qualified physician in charge of such infant shall refrain from the application of any remedy for the same, and shall immediately report such condition to the health commissioner, or to some legally qualified physician in the city, county, or town wherein the infant is cared for. Section 2.—And be it enacted: That any person or persons violating the provisions of this Act shall, on conviction, be punished by a fine not to exceed one hundred dollars, or by imprisonment in gaol not to exceed six months, or by both fine and imprisonment. Section 3.—And be it enacted: That this Act shall take effect from the date of its passage. Approved April 6th, 1894."

MEDICINE AND THE LAW IN FRANCE.

THAT the decisions of our law-courts do not invariably give satisfaction will no doubt be freely admitted by our readers, and if we may take the following case as an example they do not manage these matters much better in France. An individual named G—— was charged before the correctional tribunal at Marseilles on two separate counts: firstly, the illegal exercise of the medical art with usurpation of title; and, secondly, fraud. It was proved that the man G——, who originally had been a petty tradesman, was not only a liberated convict (ticket-of-leave man), but also completely illiterate. He nevertheless established a Curative Institute at Marseilles and by dint of strenuous advertisement succeeded in attracting a large amount of custom. No diseases were too recondite or incurable to be out of reach of his remedies. His principal medicament was a pine extract which was warranted to do many wonderful things, but he also disseminated a variety of other nostrums in the attractive form of bon-bons, syrups, pearls, and liqueurs. Evidently G——, in spite of his antecedents, was an accomplished quack, for he "captured the confidence" of numerous wealthy patients, before whom he posed as a legally qualified practitioner. According to the immemorial practice of all charlatans he maintained an imposing array of gorgeously-attired servants, and he likewise dazzled the heedless with a display of spurious medals and diplomas, which he declared were the rewards that had been bestowed upon

Hosted by Google

himself and his wares by societies and at exhibitions. In this way he contrived to extract considerable sums of money from ignorant and credulous people, whose eyes remained unopened, until at last they were compelled to acknowledge that the treatment they underwent did them more harm than good. The Marseilles tribunal found G—— guilty on the first count, acquitted him on the second, and condemned him to three months' imprisonment, with a fine of 500 francs. Against this decision he appealed, and the Minister of Justice seems also to have demanded a fresh investigation. The appeal was heard in the Supreme Court at Aix, and, to say the least of it, this, the final judgment, was peculiar. In addition to the irregular practice of medicine G—— was now pronounced guilty of fraud, the sentence of imprisonment accorded by the judges at Marseilles was confirmed, but the fine of 500 francs was remitted. As may be supposed, this ruling has excited a great deal of dissatisfaction in French medical circles. "With the greatest possible respect for the law as administered in France," says a Parisian critic, "we cannot help saying that reasonableness is not always one of its chief virtues. A correctional tribunal finds an impostor guilty on one of two counts only and inflicts a certain penalty. A court of appeal finds him guilty on both the counts and takes away half the penalty. This may be good law, but assuredly it is not good logic. Why, at this rate, if the fellow had poisoned a few of the boobies who swallowed his drugs and the primary tribunal had failed to convict him of it the court at Aix would have let him off scot-free, or perhaps even rewarded him!"

DERMATITIS CAUSED BY THE ROENTGEN RAYS.

DR. E. WAYMOUTH REID, Professor of Physiology in University College, Dundee, writing in the current number of the *Scottish Medical and Surgical Journal*, describes a remarkable personal experience of dermatitis caused by the Roentgen rays. Having to deliver a popular lecture on Roentgen's discovery he desired to obtain a photograph of his own chest or abdomen through the clothing to exhibit the contents of the pockets in addition to the skeletal structures. The exposures to which he was subjected were as follows:—Abdomen, Nov. 2nd, 1896, twenty minutes, followed by forty minutes. Chest, Nov. 3rd, fifty minutes, followed on Nov. 5th by ninety minutes. The coil was of ten-inch spark, fed by ten ampères, and the Crookes's tube ("focus" pattern) was some three inches from his waistcoat as he lay supine upon the table. On the evening of each exposure marked erythema of the skin of the abdomen and chest was noticed immediately beneath the position of the vacuum tube, and in addition slight redness of the skin of the back over an area corresponding to the exit of the rays from the body. In seventeen days the cuticle began to peel off, leaving a surface which was "raw" and "weeping," but not very painful. The discharge next became sero-purulent, and in the result some thirty square nches of cuticle were lost, but in thirty-three days healing was complete. Dr. Reid says that the apparent immunity of structures deeper than the skin is a matter of special interest. He had a sore on his chest and pimples on his back, but his lungs, so far as he knows, are unaffected.

MUNIFICENT GIFT TO THE UNIVERSITY OF ST. ANDREWS.

THE present Lord Rector of the University of St. Andrews —the Marquis of Bute,—who has for several years taken a keen interest in the development of the medical school at this ancient seat of learning, has undertaken to erect at his own cost under certain conditions four new laboratories, lecture-rooms, museums, work-rooms, &c. or the departments of anatomy, physiology, materia medica, and botany. These laboratories will be provided with all modern appliances for teaching and research purposes. The object in view is to enable students attending the medical classes at the University to spend two residential years at St. Andrews, these being required for medical graduation at all the Scottish universities. Owing to additions made last autumn to the medical teaching staff two complete *anni medici* can now be obtained at St. Andrews, qualifying courses being given in: (1) physics; (2) botany; (3) natural history; (4) chemistry; (5) anatomy; (6) physiology; and (7) materia medica. St. Andrews University aims at providing the seven fundamental subjects of the medical curriculum, and the four new laboratories, &c., will give greatly increased facilities and opportunities both to teachers and students. The new laboratories, &c., will form a most important addition to the existing natural philosophy, natural history, and chemical departments. They will inaugurate a new era in medicine at St. Andrews and, as they are to be built apart from the existing colleges on ground of their own, they will, of necessity, form the headquarters of the extended medical school there, which school will henceforth be known as the "Bute School of Medicine" in commemoration of the generous donor.

OPTIC NEURITIS AND ACUTE MYELITIS.

IN the *Archiv für Ophthalmologie* Dr. Katz relates the case of a woman aged fifty-six years who in 1894, after anxiety and a chill, began to have impairment of vision. The left disc was found to be red, the edges blurred, and the veins enlarged and tortuous. There was no swelling. The right showed similar changes, but in a milder degree. The sight, however, became worse, distinct papillitis became evident, and there were superadded symptoms of paralysis in the lower limbs and sensory impairment as high as the chest The sphincters were also affected, and in spite of treatment the paralysis persisted and the patient died a year later. At the necropsy disseminated myelitis was found to be present, there was atrophy of both optic nerves and of the chiasma, fatty heart, and interstitial nephritis. The writer refers to the coincidence of myelitis and optic neuritis—an inflammatory affection of two separate parts of the nervous system—and he adduces twenty cases of the same combination of morbid conditions. The most noteworthy point in these probably is the rapid loss of vision associated with swelling of both discs. In most cases both eyes are affected, the pupils are dilated and their reaction is lost or much impaired. Partial restoration or permanent loss of vision followed, and the myelitis was either in the dorsal or lumbar region. Dr. Katz suggests that the explanation of this curious combination is to be looked for in an affection of the sympathetic, leading to paralysis of the vaso-motor nerves with consequent hyperæmia and later atrophy of the optic nerves. The theory of an ascending meningitis he considers improbable—at least, in most cases. But probably a common cause for the two affections exists as a rule, and it is interesting to note that in fifteen out of twenty-one cases the neuritis preceded the myelitis. The identity of the histological changes in the two parts affected would also indicate a common cause, but it is impossible to give any definite opinion as to the nature of this.

LUXATION OF A SESAMOID BONE OF THE GREAT TOE.

THE value of the new photography is again exemplified by this case. The lesion appears not to have been described before, and the diagnosis was certainly impossible otherwise. The case is recorded by Thorburn.[1] A healthy labourer, aged sixty-one years, was injured on Sept. 3rd, 1895, by a weight

[1] Medical Chronicle, Nov., 1896.

Hosted by Google

falling upon the dorsum of his left foot immediately behind the first metatarso-phalangeal joint. For three weeks he was able to continue work with continuous pain. Then he became totally incapacitated by increasing pain on standing or walking. In March, 1896, he applied at the Manchester Infirmary complaining of pain in the region of the head of the first metatarsal bone of the left foot with some tenderness on pressure over the inner aspect of the bone. No physical signs of injury could be detected. Rest, counter-irritation, and the internal administration of iodide of potassium produced no result. A skiagraph showed an osseous mass between the first and second metatarsal bones. Guided by the photograph, it was thought that some resistance could be felt on deep pressure. The mass was regarded as a traumatic periosteal node. On May 3rd an incision was made in the first metatarsal space on the dorsum of the foot and the bony mass readily exposed. It was found to be distinct from the metatarsal bone, slightly moveable laterally, and attached to the flexor tendons of the great toe, being, in fact, the external sesamoid bone displaced outwards from its articulation with the metatarsal bone. Reduction was impracticable. The wound healed by primary union and the pain ceased. In July the patient was perfectly well and he is now again at work. The writer assigns no reason for the relief. We would suggest as an explanation that the case belongs to that perfectly well-recognised, though not so well understood, group in which an operation *per se* is curative of pain.

THE PHYSIOLOGICAL INFLUENCE OF ALCOHOL.

IN a valuable communication to the American Physiological Society the results of some interesting practical experiments on the effects of a daily administration of alcohol upon certain animals are recorded. The investigation was directed chiefly to ascertaining the influence of alcohol upon growth, upon mental characteristics, and upon animal activity and ability. In the first experiment two pairs of kittens as much alike as possible, the males from one litter and the females from another, were chosen. At the end of ten days' administration of alcohol the alcoholic pair had contracted severe colds, which precluded the continuation of a fair experiment. Apparently there was a distinct stunting effect, but this was probably due to the disease rather than to the alcohol. It is interesting, however, to record that the alcoholic kittens became very quiet, while playfulness, purring, and fear of dogs no longer characterised their conduct. In another series of experiments two pairs of spaniel puppies were chosen, the males brothers and the females sisters. To these gradually increasing but non-intoxicant doses of alcohol were administered, until they amounted to one and a half fluid ounces. Growth was practically normal, the alcoholic pair growing at the commencement a little faster than the non-alcoholic pair, although those grown under normal conditions were about 5 per cent. heavier than the alcoholic brother or sister. There were marked differences of behaviour. Thus the alcoholic animals were much quieter, while by means of the pedometer the alcoholic male was found to develop 71 per cent. of the daily activity of his brother and the female only 57 per cent. of her sister. A more practical test of activity consisted in throwing a ball, the dogs competing on equal terms for its possession and for the privilege of bringing it back. In this way two series of tests were made, and on 1400 and 1000 balls being thrown the alcoholic male showed an efficiency of only 32 per cent. and 44 per cent., as compared with that of his brother. In spite of the fact that on account of differences in condition no satisfactory test was possible with the females, there is, as far as it went, an obvious moral to this very interesting investigation.

GREAT BRITAIN AND THE VENICE CONFERENCE.

THE representatives of Great Britain at the forthcoming Conference upon the Plague, which will commence its sittings at Venice on Feb. 10th, will be Dr. R. Thorne Thorne, F.R.S., C.B., as technical delegate, the Hon. Michael Herbert, C.B., of the British Embassy at Rome, and formerly at Constantinople, as diplomatic delegate, and Mr. H. Farnall, C.M.G., of the Foreign Office, as assistant delegate. British India will be represented by Surgeon-General Cleghorn and probably by another physician having practical acquaintance with bubonic plague. These delegates cannot arrive from India in time for the opening of the Conference and it is probable that Surgeon-Colonel Richardson, who is familiar with the etiology of the disease, will proceed to Venice in the first instance as a deputy.

THE annual oration of the Hunterian Society will be delivered in the large theatre of the London Institution, Finsbury-circus, at 8.30 P.M. on Wednesday, Feb. 10th, by Dr. Hingston Fox, on the subject, "William Hunter (1718–1783), Anatomist, Physician, Obstetrician; with Notices of some of his Contemporaries — especially Dr. Cullen, Dr. Fothergill, and Dr. Smellie." Members of the profession will be welcomed as visitors.

A MEETING was held at the Mansion House on Feb. 1st to consider the measures to be taken for increasing the building fund of the new Royal London Ophthalmic Hospital, Moorfields, now being erected in the City-road. A list of contributions was read, including £100 from the Queen and £1000 from the medical staff of the hospital.

THE next meeting of the Epidemiological Society of London will be held at 11, Chandos-street, Cavendish-square, on Friday, Feb. 19th, at 8 P.M., when a paper will be read by Dr. J. C. McVail on the Royal Commission on Vaccination, a review of the dissentients' statement forming the text of the paper.

THE death is announced of Dr. James Ellison, surgeon and apothecary to the Queen's household at Windsor. Dr. Ellison succeeded in 1851 to his appointment in Her Majesty's household and was seventy-nine years of age.

DR. J. A. LOWSON has been sent to Bombay by the India Office to place the experience which he acquired recently in Hong-Kong at the service of those occupied in controlling the epidemic of the Plague in Indian cities.

DR. F. J. WALDO will open a discussion on "Sanitary Supervision of Shelters for the Homeless" at a meeting of the Sanitary Institute on Wednesday next at 8 P.M. Dr. Robert Farquharson, M.P., will preside.

LORD LISTER, who has for many years been consulting surgeon to the General Lying-in Hospital, has accepted the Presidency of the institution in succession to the late Earl of Darnley.

DR. GARDNER of Melbourne, Dr. Novaro of Bologna, and Dr. Lardy of Constantinople have been elected corresponding members of the Paris Société de Chirurgie.

THE Lord Mayor will preside at the annual court of the Royal Hospital for Diseases of the Chest, City-road, E.C., on March 15th.

Obituary.

SIR THOMAS SPENCER WELLS, BART., F.R.C.S., &c.,

PAST PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND; SURGEON TO HER MAJESTY'S HOUSEHOLD; AND CONSULTING SURGEON TO THE SAMARITAN FREE HOSPITAL FOR WOMEN.

WE deeply regret to have to announce the somewhat sudden, but not altogether unexpected, death of Sir Spencer Wells, which occurred on Sunday last at Cap d'Antibes.

Sir Spencer Wells was born at St. Albans, Hertfordshire, on Feb. 3rd, 1818, being the eldest son of Mr. William Wells, who, as well as his father before him, had resided in that city. At an early age he turned his attention to the study of natural science, taking the greatest possible interest in the habits of all manner of living creatures, and when but a boy he expressed his determination of following the medical profession. In this choice he was confirmed by his parents, who saw clearly that not only did his tastes lie in that direction, but that he possessed the very characteristics which were calculated to lead him to success in the profession. He was quite a lad when he became a pupil of Mr. Michael Sadler, a general practitioner at Barnsley, in Yorkshire, then by no means the populous town into which it has developed, but even at that time an important centre of the textile and linen industry. The weaving machinery was in those days imperfect, and accidents of a more or less severe character were of a frequency which gave many opportunities for the observation of injuries which did not as a rule come under the notice of the young pupil of a general practitioner. After this initiation Thomas Spencer Wells, then a youth of seventeen, became a pupil of, and unqualified assistant to, a parish surgeon at Leeds. While residing under this gentleman's roof he had the opportunity of attending the lectures of William Hey, "the second," who did so much to promote the interests of medical education in the northern counties and who took so prominent a part in the establishment of the Leeds School of Medicine. He likewise attended the classes of the elder Teale, an equally eminent surgeon in Leeds. Besides the teachings of these two men, to whose influence he always referred with the warmest feelings of gratitude, he had the privilege of attending the surgical practice of the Leeds Infirmary, an institution at that time among the foremost centres of operative surgery in the provinces.

SIR THOMAS SPENCER WELLS, BART., F.R.C.S.,
PAST PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

He stopped little more than a year in Leeds and then proceeded to Trinity College, Dublin, and during his residence there made the best use of his time, attending the lectures of Sir Philip Crampton in Surgery and those of Arthur Jacob, the anatomist and ophthalmic surgeon. He left Dublin in 1839 and proceeded to St. Thomas's Hospital, London, where Joseph Henry Green, Benjamin Travers, and Frederick Tyrrell were the surgeons and Dr. Williams, Dr. Roots, and Dr. Burton the physicians. At the end of his first session at St. Thomas's Hospital Spencer Wells won the prize offered for the most complete and detailed reports of the post-mortem examinations made of the patients dying in the wards of the hospital during the session. After another year's attendance on the practice of St. Thomas's Hospital he obtained, in 1841, the Membership of the Royal College of Surgeons of England, and joined the navy as a surgeon. There was no war being carried on at the time, so that he had no prospect of immediate adventure or even of great activity. He was ordered to Malta, where he served in the Naval Hospital for six years, during which time he was permitted, besides his official or service duties, to frequently meet in consultation and to assist many of the resident medical men, both English and Maltese. Although he saw much practice and did much good work at Malta he afterwards stated that he saw only one case there which raised even a suspicion in his mind of the existence of ovarian disease.

Having served six years at Malta, he left the navy and in 1848 proceeded to Paris with the view of perfecting his studies in pathology. Magendie was then at the height of his fame and Claude Bernard had for some years been advancing towards the position to which he afterwards attained as a teacher. Many English practitioners and students were in Paris at this time, having been attracted thither by the fame of the great array of prominent thinkers and experimentalists, who, in their turn, attracted by the facilities and encouragements offered for the experimental discovery of the true nature of disease, had settled there. Among Spencer Wells's acquaintance in Paris was the late Dr. Waters, afterwards of Chester, who first directed his attention to the operation of ovariotomy. The two had many discussions on the subject, and ultimately concluded, as had previously been almost universally acknowledged in England, that it was an unjustifiable operation. It was not until ten years later that Wells returned to the subject in earnest; and up to the time of his residence in Paris (1850), as he afterwards stated, he had never, so far as he could remember, encountered a single case which he could safely assert to be ovarian disease either during his student days in Barnsley, Leeds, Dublin, or London, or during his stay in Malta and Paris.

On his return to London in 1853, Spencer Wells settled down in practice, and in a short time attained considerable success, turning his attention more especially to obstetric work, although he showed a remarkable aptitude for, and achieved some good work in, ophthalmic surgery, for which branch of his art his mechanical ingenuity and manipulative dexterity rendered him particularly suited. In 1854 he became connected with the Samaritan Free Hospital for

Hosted by Google

Women and Children in the Marylebone-road, which had been established but seven years, and was little more than a dispensary for the diseases of women, not being provided with in-patient accommodation. With this institution he remained connected throughout his life. It was during this period of his career that, for a time, he edited the *Medical Times and Gazette*, and it was in his editorial capacity that he came into contact with many prominent members of the profession who were afterwards closely associated with his work. The man who probably exerted the greatest influence over his future was Mr. Baker Brown, the gynæcologist, who was at this time essaying the revival of the generally condemned operation of ovariotomy Although John and William Hunter had discussed the advantages and disadvantages of the operation and the methods of performing it, they had never put their theories into practice. Aston Key and Bransby Cooper had performed it a few times at Guy's Hospital, but their results had been by no means such as to encourage the advocates of the operation. It was not, however, until Charles Clay appeared as an advocate of the operation that it became in any way recognised as coming within the realm of practical and useful surgery, and even then the untoward results of a terribly large percentage of cases caused it to be looked upon with suspicion if not with absolute disapproval by the bulk of British practitioners.

In April, 1854, Spencer Wells, in company with his friend, Mr. T. W. Nunn of the Middlesex Hospital, assisted Mr. Baker Brown in his eighth case of ovariotomy. This was the first time that Spencer Wells had seen the operation performed, and its result, like that of six others of Baker Brown's first nine cases, was not encouraging. In discussing the operation afterwards Mr. Baker Brown remarked, "It's the peritonitis that beats us," for it was chiefly in the matter of after-treatment that the results of the operation formed such a discouraging picture. Temporarily disheartened by his ill-success in seven out of nine cases, Mr. Baker Brown for a time abandoned all hope of introducing the operation, although he was in his own mind convinced of its reasonableness and ultimate utility. It was not until 1857, however, that Spencer Wells himself attempted the operation, and this he did contrary to the express advice of his friend, Mr. Baker Brown, who nevertheless assisted him. The result of this his first venture was not encouraging, for he lost his case. He was not discouraged by this untoward beginning, but persevered, and in the following year his hopes were realised by the entire success of his second case. From that time forward the results obtained by him are a portion of the surgical history, not only of the century, but of all time.

It is not only on account of his mechanical dexterity in a particular operation that Sir Spencer Wells deserves to have his name kept in honoured remembrance. At the time when he turned his attention to ovariotomy the operation was so fatal as to be generally regarded as unjustifiable; and no common force of character was required to persevere with the operation. Feeling assured with the instinct of genius of the possibility of its ultimate success he says himself, "On taking up this subject as a matter of study and trial, just at the crisis when obloquy was the thickest and opposition the strongest, I felt that nothing but the most open frankness would carry conviction of success, or in case of failure justify the operation. ..... I therefore pledged myself to make known through the press all that I did and all that befell me" Sir Spencer Wells deserves the greatest credit both for having at that time the courage to make public his failures as well as his successes and also for recognising that only in such a way could it be hoped to establish ovariotomy as a justifiable operation. There can be no doubt that the large number of abdominal operations performed at the present day owe their inception to ovariotomy, and to Sir Spencer Wells belongs the credit, not of inventing ovariotomy, but of taking the principal share of the work involved in establishing that operation on a recognised basis.

In 1857 he became Lecturer on Surgery at the Grosvenor-place Medical School, which eight years afterwards became merged in the school of St. George's Hospital. Between the time when Spencer Wells first turned his attention to ovariotomy and the first occasion when he practically essayed it his energies were directed for the space of a year or more to a very different kind of work. Shortly after the war broke out in the Crimea he temporarily abandoned his work at the Samaritan Hospital and his private practice and proceeded to Smyrna, where he became surgeon to the British Civil Hospital there as well as at Renkioi, whither he afterwards proceeded. He saw a great class of injuries which were almost entirely new to him, and in the course of his work had the opportunity of attending to many abdominal wounds, experience which afterwards proved most useful in his surgical work. He frequently stated in after years that it was during the war that he realised that the peritoneum would stand much rougher handling than he had previously imagined, and it was this knowledge in great measure that reassured him in the operation and gave him the boldness which characterised his later work and which results amply justified. At Renkioi he was closely associated with Dr. Parkes, who was one of his oldest professional friends.

Sir Spencer Wells's literary works comprise a number of treatises and contributions which have been of great practical utility to the medical profession both in England and abroad. In 1851, after his term of service had expired for a year or two, he published a useful "Scale of Medicines for use in the Merchant Marine," and while in London previously to the outbreak of the Crimean War he contributed a valuable dissertation on "Gout and its Complications" (1854). It was while he was occupying the chair of Surgery at the Grosvenor-place School that he delivered his lecture on "Cancer and Cancer-curers," which was printed in the *Medical Times and Gazette* and afterwards published in pamphlet form in 1860. Among the archives of ovariotomy Sir Spencer Wells's works rank among the most valuable contributions; based as they were upon his personal experiences and being accounts in tabular form of the work of the foremost ovariotomist of the time, they form in reality little less than the history of the revival of this operation in England. In 1865 he published his first work on this subject under the title of "Diseases of the Ovaries," and in it he not only provided valuable statistics supplied by his earlier years as a successful ovariotomist, but conveyed many inestimable hints towards the diagnosis of ovarian tumours. Simultaneously with this work he published "A Note-book for Cases of Ovarian and other Abdominal Tumours," which was intended to assist practitioners in classifying their cases of these disorders and thus increasing the sum of statistical knowledge on this subject. This note-book has been through seven editions—a fact which testifies to its practical value and general utility. In 1882 an enlarged work founded on the two foregoing publications appeared, and was chiefly interesting in that it contained, in both a descriptive and tabular form, an accurate and detailed account of the personal work of the great ovariotomist. Its scope was to all intents and purposes limited to what its author had himself seen and done. A short history of the revival of ovariotomy was printed in 1884 and a second edition was called for in the following year. A considerable portion of his works on the subject of the operation with which his name is so intimately associated has been translated into the German language by Dr. R. von Volkmann and enjoys a wide popularity on the Continent. He was the author of a very large number of interesting and valuable communications to the Obstetrical and other societies as well as of numerous contributions to the medical press.

His opinions on the question of cremation were very decided, and in 1885, when the controversy begun by Sir Henry Thompson and others was at its height, he wrote an eloquent and outspoken letter to the *Times* advocating cremation, not only from a sanitary point of view, but pointing out what an impetus its adoption would give to the arts. Cinerary urns have in all countries where the practice is carried out been amongst the most beautiful features of the temples and other resting places of the departed. He likewise lectured at the Parkes Museum of Hygiene on the subject and brought similar arguments to bear.

It was during his residence in Malta—namely, in 1844—that the Royal College of Surgeons of England conferred on him the honorary degree of Fellow, the order of Fellows having been created by the new Charter. With the College of Surgeons his connexion was thenceforth of a most intimate character. In 1871 he was elected a member of the Council, in 1877 Hunterian Professor of Surgery and Pathology, and in 1879 a Vice-President. On the retirement of Sir Erasmus Wilson from the Presidency in 1883 Spencer Wells was elected to the chair, which he filled for a year. In 1883 he delivered the Hunterian Oration, and five years later held the post of Morton Lecturer on Cancer and Cancerous Diseases. In 1890 he was Bradshaw Lecturer.

Sir Spencer Wells was made an honorary Fellow of the King's and Queen's College of Physicians of

Hosted by Google

Ireland, and when the Universities of Leyden and Bologna respectively celebrated the third and eighth centenaries of their existence, both of these bodies conferred on him the honorary degree of M.D. He was likewise honoured by the Doctorate of the University of Charkof and was a Knight Commander of the Norwegian Order of St. Olaf. He was a Fellow of the Royal Medical and Chirurgical Society, of the Pathological Society, of the Medical Societies of Paris, Moscow, and Stockholm, and a Member of the Obstetrical Societies of London, Berlin, and Leipzig. On May 11th, 1883, Her Majesty conferred on him the honour of a baronetcy of the United Kingdom in recognition of his services to medical science and to humanity. Sir Spencer Wells was a deputy-lieutenant for the county of London. He married in 1853 Miss Elizabeth Wright, daughter of Mr. James Wright, solicitor, of New Inn, by whom he leaves five daughters and one son, Arthur Spencer Wells, who succeeds to the title.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent medical men are announced:—Dr. L. Calori, Professor of Anatomy in the University of Bologna.—Dr. Pantaleo, Emeritus Professor of Midwifery in Palermo.—Dr. José Maria Vilches, Professor of Clinical Medicine in the Cadiz Medical School.—Dr. W. H. Pancoast, Professor of Anatomy and Clinical Surgery in the Philadelphia Medico-Chirurgical College.—Dr. Theodore Wormley, Professor of Chemistry and Toxicology in the University of Pennsylvania.—Dr. Karl Herrimann Sätherberg of Stockholm, well known not only for his works on orthopædics but as a poet.

STATISTICAL REPORT OF THE HEALTH OF THE NAVY FOR THE YEAR 1895.

OUR Royal Navy has of late years undergone, and is still undergoing, a considerable increase to its strength in the way of ships, and it is a matter of some consideration at the present time where we are to get the men to man them—for we need scarcely add that the seamen of our fleet have to be a strong, healthy, highly-trained body of men such as cannot be picked up promiscuously or every day.

The head of the Medical Service of the Navy tells us in the report under notice that the returns for the total force for 1895 may be regarded as satisfactory on the whole. There has been an increase in the number of cases of disease compared with the previous year, but this is attributed principally to the increased prevalence of influenza in the Home, China and Cape of Good Hope, and West Coast of Africa stations.

The total force in the Service afloat in 1895 was 67,960 officers and men, of whom 59·9 per cent. were between the ages of fifteen and twenty-five, 29·04 per cent. between twenty-five and thirty-five, 9·47 per cent. between thirty-five and forty-five, and only 1·57 per cent. were above forty-five years of age, so that our Navy is, as it should be, mainly a young one.

The ratio of invaliding in 1895 was 25·26 per 1000, which is lower, with the exception of 1889, than that recorded for any year since 1856, when, we are told, the present system of statistical reports was started. The ratio of deaths in 1895 (6·6 per 1000) was a slight increase on that of 1894, but somewhat less than the average of the last eight years. This increase is explained by being chiefly attributable to the foundering of the pinnace of the *Edgar* at Chemulpo, with the loss of forty-eight officers and men. The total number of cases of disease and injury entered on the sick-list gives a ratio of 959·32 per 1000, being an increase of 40·12 on that of 1894, but a decrease of 14·54 per 1000 as compared with the average ratio of the last eight years. The average number of daily sick in 1895 was 2789·32, which is in the ratio of 41·04 per 1000; and it is calculated that the average loss of service from disease and injury amounted to 14·98 for each person.

Taking the distribution of sickness throughout the different stations it is stated that the lowest sick-rate was on the South-East Coast of America station and the highest on the East Indies station. The ratio per 1000 of men sick daily on the Home station was 40·43; Mediterranean, 37·19; North American and West Indian, 36·52; South-East coast of America, 33·38; Pacific, 41·12; Cape of Good Hope and West Coast of Africa, 48·85; East Indies, 49·9; China, 45·12; Australian, 44·87; and in the irregular force, 43·06.

The naval operations connected with expeditions on the East and West Coasts of Africa gave rise to a great increase of sickness from malarial fevers, more especially those conducted up the Brass River.

Turning to some of the special kinds of disease and inefficiency, we find there were 10,292 cases of venereal disease returned during the year under report. Of these, 3296 were of primary and 1651 of secondary syphilis. The number invalided for these diseases was 173 and there were 5 deaths. Upwards of 5000 cases are recorded at the home stations.

The number of cases comprised under the heading of diseases of the respiratory system in the total force is 8109, the invalidings number 223, and the deaths 81.

There was a severe outbreak of measles on board the *Britannia* in 1895, fifty-two cases having occurred, three of which ended fatally.

Sixty-five cases of enteric fever occurred, distributed throughout twenty-four ships at the home station, fifteen of which died.

In the Mediterranean Squadron, composed of thirty-three vessels in all, with a mean force of 10,270, the admissions for disease and injury during the year were 9990. Among the fevers there were 505 cases of simple continued fever and 82 of enteric fever, 557 of influenza, 9 of dysentery, and 11 of mumps. Sixteen cases of enteric fever ended fatally and 17 were invalided.

The health of the squadron on the East Indies station in 1895, judging from the invaliding rate (42·47 per 1000), the death-rate (10·21), which was 3·26 higher than 1894, and the daily average number of men ineffective, was not so favourable as in the preceding year.

Scattered here and there through these reports are some interesting medical notes and cases which give occasion for regret that they are not more frequently encountered. Surgeon F. H. A. Clayton, M.B., of the *Thrush*, has some excellent remarks on West African fevers in connexion with the organism discovered by Laveran and studied so successfully by Golgi, and of the value of that discovery in settling the diagnosis of certain obscure cases of malarial disease. Surgeon John Lowney, of the *Redpole*, on the China station, describes a case in which a hydatid cyst was expelled from the stomach—rarely the seat of that parasite. Surgeon V. G. Thorpe, of the *Penguin*, and Surgeon James M. France, of the *Ringdove*, have also some good observations on malarial fevers, and Surgeon E. A. Penfold, M.B. Edin., alludes to a curious case of poisoning from the consumption of a fish caught off Malo Island, New Hebrides.

The information in these naval medical reports is mainly statistical, and that which is added of an explanatory character, or as illustrative of the type and nature of the diseases at the different stations, is generally of the most condensed kind. The interest of these reports would, in our opinion, be very much increased by more extended extracts from reports made by medical officers whose observations, derived from so many different climates and parts of the world, must often be of value.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE ordinary quarterly Comitia of the Fellows of the Royal College of Physicians was held on the 28th ult., the President, Dr. S. WILKS, F.R.S., occupying the chair.

The PRESIDENT stated that since the last meeting he had taken part in the award of the Gilbert Blane medal, which had been bestowed on Surgeon E. G. Thorne. He had nominated Dr. Markham Skerritt as the Bradshaw Lecturer for 1897 and Dr. S. M. Copeman as Milroy Lecturer for 1898. The President also drew attention to the dies of the Weber-Parkes medal, prepared by Mr. Boucher from designs by Dr. H. Weber. Replicas of the medal were on the table and were much admired by the Fellows.

The following gentlemen were admitted to the Membership of the College:—Jas. Barr, M.D. Glasg., A. P. Beddard, M.R.C.S., L.R.C.P. Lond., G. H. A. C. Berkeley, B.A., M.B. Camb., C. R. Box, M.D. Lond., R. J. McL. Buchanan, M.D. Vict., M. Craig, M.A., M.B. Camb., J. J. Perkins, M.A., M.B. Camb., and R. A. Young, M.D. Lond.

Hosted by Google

Licences and certificates were granted to the successful candidates for the recent examinations for the Licence and for the Diploma of Public Health.

Communications were read:—(*a*) From the secretary of the Royal College of Surgeons of England reporting the proceedings of its Council. (*b*) From Mason College, Birmingham, inviting the College to send a representative to serve on its newly-constituted Council. The President nominated Dr. W. H. Dickinson for that office. (*c*) Requests for loans of pictures for public exhibition, which had been declined in accordance with the invariable rule of the College.

A report from the Council embodying the following resolution was unanimously adopted:—

"That when the College decides to return the diploma of Membership to any gentlemen who has been permitted to withdraw, in his own interest, from the status of a Member, the name of such reinstated Member shall be placed at the bottom of the list of Members of the College."

"That in future, when application is made for the restoration of a diploma of Membership which has been surrendered, notice of such application shall be placed on the agenda paper for the next quarterly Comitia, with a request that any objections to such restoration should be sent by Fellows to the Censors' Board for their consideration before the application is submitted to the vote of the College at the following quarterly Comitia."

On the nomination of the Council Dr. Sansom, Dr. Mitchell Bruce, Dr. Allchin, and Dr. F. Taylor were elected to the Council to fill seats caused by the retirement by rotation of Dr. R. Liveing, Dr. Duffin, Dr. Thorne Thorne, and Dr. F. T. Roberts.

The report of the Special Committee appointed on Oct. 29th to consider the desirability of including the subject of bacteriology in the course of study and examination for the Licence was read. The Committee, after full inquiry into the extent of teaching in bacteriology both in foreign countries and in the schools of the United Kingdom, were of opinion that the subject should be included. It was pointed out that the inclusion of pathology in the subjects of examination covered that of bacteriology, and as regarded the course of study they recommended that after the words, "including practical instruction in pathological histology," the words, "and in bacteriology," should be added to the regulation bearing on instruction in pathology.—The adoption of the report was moved by Dr. PAVY, seconded by Dr. CHURCH, and carried unanimously.

The PRESIDENT offered for the acceptance of the College, on behalf of Lady Reynolds, a portrait of the late President, Sir J. Russell Reynolds, Bart., M.D., LL.D., F.R.S., by Mr. Sydney Hodges, painted about 1883. The thanks of the College were voted to Lady Reynolds by acclamation.

A report from the Bisset-Hawkins Memorial Committee was read submitting a design by Dr. H. Weber for the medal it was proposed to institute. The report was adopted.

Sir DYCE DUCKWORTH, treasurer of the College, read a report of the proceedings which took place on the occasion of the removal of the remains of Louis Pasteur to the Institut Pasteur on Dec. 26th, 1896, he having attended the ceremony as representative of the College.—The PRESIDENT, in expressing the thanks of the Fellows to Sir Dyce Duckworth, remarked that it was no credit to this country that it had given no tribute to "that great man," Louis Pasteur.

Reports were also received from the representative of the College in the General Medical Council (Sir Dyce Duckworth) from the Conjoint Finance Committee, from the College Finance Committee, the Committee of Management, the Laboratories Committee; the annual report of the Examiners for the Licence was also presented.

THE BATTLE OF THE CLUBS.

THE *Montreal Medical Journal* for December, 1896, publishes some resolutions passed (1) by the Provincial Board of Medicine of Quebec and (2) by the medical men of Santa Clara, county California. The following are the Quebec resolutions:—

[TRANSLATION.]

PROVINCIAL BOARD OF MEDICINE.

Extract of the minutes of the Provincial Board of Medicine, held at Quebec, 12th September, 1895, in the new rooms of the School of Medicine of Laval University.

Proposed by Dr. S. Gauthier, seconded by Dr. Beausoleil, and resolved, "That a committee composed of the members of the Legislature, together with the proposer and seconder, be authorised to study the rules and constitution of the several friendly societies doing business in the province of Quebec, and that it be resolved that this committee take means to do away with the despotic rules that these associations calling themselves philanthropical impose upon the medical profession." "That the College of Physicians and Surgeons of the province of Quebec express their disapproval of the conduct of members of this College who make engagements with these societies to attend the members of the lodges for a salary agreed upon in advance." "That it is derogatory to professional honour and ethics to be bound in all cases to make known the name, the cause, and the nature of the sickness of the members of these associations." "That this committee confer with the several managements of these associations of mutual help, so as to cause the withdrawal from their constitutions of the clauses requiring the doctors to certify, even under oath, the causes of the demands for benefits from their members." These obligations being a cause of crying abuse in a great number of cases, at the same time that they expose the medical profession to popular discredit.

True copy. (Signed) A. G. BELLEAU,
Secretary C.M. & C.P.Q.

The resolutions of the Californian medical men are much more drastic, and run as follows. The resolutions are prefaced by a letter from the secretary:—

Resolutions Adopted by the Physicians of Santa Clara County.

Whereas rendering professional service at a stipulated fee per capita per annum is derogatory to the medical profession, we, the undersigned physicians and surgeons of Santa Clara County, California, enter into the following agreement:

1st. We mutually, jointly, and individually, pledge our word of honour not to enter into any contract, or agreement, or renew any existing contract or agreement, either written, verbal, or implied, to render medical or surgical services to any lodge, society, association, or organisation. 2nd. We will not render medical or surgical services to the members of the above-mentioned bodies for less compensation than we charge the general public for similar services. 3rd. This agreement shall not be construed to affect existing contracts between physicians and surgeons and the above-mentioned bodies. 4th. These pledges shall take effect and be in force for a term of three (3) years from and after May 22nd, 1896.

"This agreement shall not apply to hospitals and purely public charitable institutions. The duty of the standing committee shall be to interview new coming physicians, &c., and, in general, to carry out the purposes of the agreement. Communications may be addressed to the chairman or secretary.

The Californian practitioners' resolutions are very admirable, and will, no doubt, bring the "clubs" to see reason, if, and "there is much virtue in an 'if,'" the whole 124 members stick to one another. Perhaps we are somewhat behind the age in this country; but here it generally happens that if a "club doctor" gives up his appointment in obedience to the wishes of his fellow practitioners some other medical man from a distance steps into the post thus vacated. On the whole we think the Canadian plan the better, at first at any rate, but we wish our colleagues, both there and in California, every success in their struggle for, to quote the *Daily Chronicle*, "the right of combination."

ARMY MEDICAL SCHOOL, NETLEY.

TERMINATION OF THE SEVENTY-THIRD SESSION.

THE seventy-third session of the Army Medical School, Netley, was brought to a close on Jan. 30th, when the prizes were distributed by Surgeon-Major-General J. Jameson, Director-General of the Army Medical Department, in the presence of the military and nursing staff of the Royal Victoria Hospital and a considerable company, which included Surgeon-Major-General Cuffe, C.B., Principal Medical Officer, Portsmouth.

Surgeon-Colonel J. Lane Notter, M.D. Dub,, secretary to the Senate of the School and Professor of Military Hygiene. read a report of the work of the session and the result of the examinations, of which the following is an abstract:—

"A *précis* of the reports which the professors of the Army Medical School have addressed to the Secretaries of State for War and India respectively is contained in the printed slips which have been distributed to all those who are present here to-day. It indicates the position of the surgeons on probation of the British and Indian Medical Services as determined by the results of the London and Netley examinations. I am able to report that the work of the session has been satisfactory; twenty-four out of the twenty-five surgeons on probation who have undergone the final examination have proved themselves fitted to receive Her Majesty's commission. In general ability they are as a whole of fair

Hosted by Google

average. Their conduct while passing through the school has been excellent, and there has been a good tone throughout the school. The Herbert Prize, consisting of £20, given in memory of the late Lord Herbert of Lea, who, when the Right Honourable Sidney Herbert, was president of the Royal Commission which resulted in the foundation of the Army Medical School, and which is awarded at the end of each course of instruction to the surgeon on probation who has evinced the highest proficiency in the special subjects taught at the Army Medical School, is on this occasion awarded to Surgeon-on-Probation Stammers, of the Army Medical Staff. The Martin Memorial Gold Medal, which is given to the surgeon on probation who takes the highest place in Military Medicine, and is intended to commemorate the late Sir Ranald Martin, is awarded to Surgeon-on-Probation Woolley, of the Indian Medical Service. The Professor of Medicine desires to call attention to the names of Surgeons-on-Probation McArdle and Stammers as having particularly distinguished themselves throughout the examination in military and tropical medicine. The Parkes' Memorial Bronze Medal, which is given to the surgeon on probation who takes the highest place in Hygiene, and which forms part of a memorial to commemorate the great services of the late Professor E. A. Parkes, has been won by Surgeon-on-Probation Stammers of the Army Medical Staff. The second prize in hygiene, a book presented by Mrs. de Chaumont in memory of her husband, the late Professor F. de Chaumont, F.R.S., is awarded to Surgeon-on-Probation McArdle of the Indian Medical Service, who has gained the second place in this department of study. I desire also to make mention of Surgeons-on-Probation Marriott and Woolley, who have also particularly distinguished themselves in military hygiene. The Montefiore Prizes, two in number, which were founded by Mr. Nathaniel Montefiore, were awarded to Surgeons-on-Probation Stammers and Hugo. The first prize consists of a medal with a cheque for £21; the second of a revolver. The Professor of Military Surgery desires that the names of the following gentlemen shall be honourably mentioned in this department of study: Mr. J. M. Woolley, Mr. E. W. Bliss, and Mr. A. A. F. McArdle. The Prize in Pathology, a prize of books, presented on this occasion by the Director-General, has been won by Surgeon-on-Probation G. E. F. Stammers of the Army Medical Staff, while the names of the following gentlemen are worthy of special mention as pathologists: Mr. C. A. Lane, I.M.S.; Mr. C. F. Wanhill, A.M.S.; and Mr. T. B. Kelly, I.M.S. The Maclean Prize of books, presented by Surgeon-General Maclean, so long Professor of Military Medicine in the school, is awarded to Surgeon-on-Probation A. A. F. McArdle, of the Indian Medical Service, who has gained the highest marks in clinical and ward work."

The Director-General then presented the prizes and delivered an address, an abstract of which will be found at p. 366 of our present issue. The proceedings were brought to a close by a few words from Surgeon-Major-General W. Nash, M.D. Edin., Principal Medical Officer, Netley, who thanked the Director-General for presiding and presenting the prizes and for his admirable address. The Director-General, the guests, and staff were subsequently entertained at luncheon by the officers of the Army Medical Staff.

The following are the names of the surgeons on probation of the Medical Staff of the British Army and Indian Medical Service who were successful at both the London and Netley examinations. The final positions of these gentlemen are determined by the marks gained in London added to those gained at Netley, and the combined numbers are accordingly shown in the lists which follow:—

ARMY MEDICAL STAFF.

	Combined marks.		Combined marks.
1. G. E. F. Stammers ...	5889	7. E. W. Bliss	4004
2. C. F. Wanhill	5006	8. M. M. Rattray	3999

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Staffordshire County Sanitary District.—The administrative county of Staffordshire contains so many sanitary districts that to make a separate report upon each would, Dr. Reid tells us, be a difficult matter, and hence he continues his former plan of dealing with the district report under different headings. In his summary of the work of the sanitary committee for the year ended July, 1896, Dr. Reid, in referring to certain Local Government Board inquiries as to sewage disposal, suggests that further efforts should be made to induce the Local Government Board to give notice of all such meetings to the Council; at present, he states, he hears of them only by chance. Conferences have been held during the year under review in reference to hospital accommodation and Dr. Reid hopes that more than one joint hospital board will be formed under the Isolation Hospitals Act. The reports of the district medical offices of health contain, we are told, evidence of much work done in the direction of substituting the water-carriage system for the privy method of excrement disposal, and activity has also prevailed in the matter of closing private wells where public supplies are available. As a means toward the reduction of infantile mortality Dr. Reid suggests that the Council, through the Technical Instruction Committee, might institute lectures in domestic hygiene at suitable centres throughout the county. It is to be hoped that if this excellent suggestion is acted upon by the Council efforts will be made to attract mothers to the lectures by the distribution of printed leaflets in the neighbourhood; perhaps a well-qualified lady lecturer would be able to instil some useful knowledge into the minds of the mothers. In connexion with this subject it may be remarked that in seven districts in the county of Staffordshire the infantile mortality exceeded 200 per 1000 births. Reference is made by Dr. Reid to the prejudice which exists in certain districts against taking advantage of isolation accommodation, and he very properly insists upon the necessity of making such accommodation as attractive as possible. Certainly we should be sorry to be "isolated" in some hospitals for infectious disease with which we are familiar. The adoption of compulsory notification is gradually extending in the county, but there are still some 89,000 persons unprotected by the Act. The cost of notification is, Dr. Reid shows, not ruinous, it having amounted to but £1 2*s.* 8*d.* per 1000 inhabitants during 1895. It is gratifying to learn that the inspection of meat, dairies, and cowsheds is receiving more attention than heretofore, as also is the sanitary control of factories and workshops.

Wandsworth Sanitary District.—The medical officers of health for this district in their current conjoint report express the opinion that the usual estimate of the amount of isolation hospital accommodation which would be necessary to cope with measles in London is a much exaggerated one. They point out that an average stay in hospital of three weeks would probably suffice, as contrasted with the very much longer period required for scarlet fever. At the present time they remark that no case of measles, however bad and however poorly provided for at home, can be received into any hospital or infirmary.

Bedfordshire County Sanitary District.—In his annual report for 1895 Dr. Leonard Wilde, in commenting upon the death-rate of the county, points out that there is an undue tendency among medical officers of health in Bedfordshire to reduce the death-rates of their districts through the too liberal exclusion of deaths. He observes that although the deaths occurring within a district among persons not belonging thereto are studiously excluded, no such care appears to be exercised in adding the deaths which rightly belong to the district, but which have actually occurred outside it. As a means of illustrating his point Dr. Wilde observes that, although 2683 deaths were registered in the county, only 2526 were dealt with by medical officers of health. Notification of infectious diseases is not yet complete in Bedfordshire, and hence it is impossible to ascertain the exact amount of infectious disease present in the county. In one of the recalcitrant districts it was

Hosted by Google

seriously urged that notification was unnecessary inasmuch as when infectious disease prevailed notification could be adopted in a few hours. These arguments show a very poor appreciation of the fundamental principles of preventive medicine. Dr. Wilde reminds the County Council that although he endeavours to carefully summarise the district reports it is obvious that sanitary defects may exist of which he can only become cognisant after a personal survey of the county. Certainly the survey which was undertaken by Dr. Williams, the county medical officer of health of Glamorganshire, has had not only the effect of making him familiar with the subject upon which he annually writes, but has also stimulated public action in the local districts. In some senses the Bedfordshire County Council are an advanced body, and we read with pleasure that with the view of reducing infantile mortality they have instituted lectures to women through their Technical Instruction Committee. Isolation accommodation in Bedfordshire is still practically at a standstill, but Dr. Wilde seems rather to favour the suggestion that the County Council should provide hospitals for small-pox throughout the county, and allow the local authorities to provide hospitals for ordinary infectious disease. There is very much to be said for this suggestion, as the provision of separate small-pox hospitals by each authority is hardly to be expected.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6563 births and 4338 deaths were registered during the week ending Jan. 30th. The annual rate of mortality in these towns, which had been 19·2 and 19·7 per 1000 in the two preceding weeks further rose last week to 20·6. In London the rate was 19·9 per 1000, while it averaged 21·1 in the thirty-two provincial towns. The lowest rates in these towns were 10·8 in Croydon, 14·7 in Halifax, 15·9 in Preston, and 16 0 in Gateshead; the highest rates were 25·3 in Birmingham, 25·7 in Liverpool and in Salford. 27·5 in Wolverhampton, and 33 6 in Plymouth. The 4338 deaths included 366 which were referred to the principal zymotic diseases, against 378 and 386 in the two preceding weeks; of these, 120 resulted from whooping-cough, 83 from diphtheria, 58 from measles, 38 from scarlet fever, 38 from diarrhœa, 29 from "fever" (principally enteric), and not one from small-pox. The lowest death-rates from these diseases were recorded in Brighton, Norwich, and Birkenhead; and the highest rates in Burnley, Salford, Blackburn, Nottingham, and Wolverhampton. The greatest mortality from measles occurred in Bradford, Gateshead, Plymouth, and Nottingham; from scarlet fever in Salford and Croydon; and from whooping-cough in Salford, Bristol, Burnley, Blackburn, and Wolverhampton. The mortality from "fever" showed no marked excess in any of the large towns. The 83 deaths from diphtheria included 53 in London, 6 in Birmingham, 4 in West Ham, 3 in Wolverhampton, 3 in Oldham, and 3 in Liverpool. No fatal case of small-pox was registered during the week under notice, either in London or in any other of the thirty-three towns. There were 9 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, Jan. 30th, against 3 and 2 at the end of the two preceding weeks; 7 new cases were admitted during the week. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 3311, against 3597, 3414, and 3354 on the three preceding Saturdays; 254 new cases were admitted during the week, against 290, 208, and 249 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 306 and 325 in the two preceding weeks, further rose to 355 last week, but were 240 below the corrected average. The causes of 78, or 1·8 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leicester, Salford, Bradford, Leeds, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Liverpool, Blackburn, and Huddersfield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 21·9 and 24·6 per 1000 in the two preceding weeks, declined again to 24·3 during the week ending Jan. 30th, but was 3·7 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 18·0 in Leith and 19·8 in Dundee to 29·0 in Perth and 30·5 in Greenock. The 723 deaths in these towns included 28 which resulted from measles, 28 from whooping-cough, 11 from diarrhœa, 7 from "fever," 5 from scarlet fever, and 2 from diphtheria. In all, 81 deaths resulted from these principal zymotic diseases, against 75 and 89 in the two preceding weeks. These 81 deaths were equal to an annual rate of 2·7 per 1000, which exceeded by 1·0 the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 45, 28, and 36 in the three preceding weeks, declined again to 28 last week, of which 24 occurred in Glasgow and 2 in Paisley. The deaths from whooping-cough, which had been 26 in each of the two preceding weeks, rose to 28 last week, of which 19 were recorded in Glasgow and 7 in Edinburgh. The 7 deaths referred to different forms of "fever" showed a slight further increase upon recent weekly numbers, and included 3 in Glasgow. The fatal cases of scarlet fever, which had been 10, 3, and 6 in the three preceding weeks, were 5 last week, of which 4 occurred in Edinburgh, where the 2 fatal cases of diphtheria were also recorded. The deaths referred to diseases of the respiratory organs in these towns, which had been 162 in each of the two preceding weeks, rose to 190 last week, and exceeded by 48 the number in the corresponding period of last year. The causes of 44, or more than 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 34·8 and 43·9 in the two preceding weeks, declined again to 42·4 during the week ending Jan. 30th. During the past four weeks of the current quarter the death-rate in the city has averaged 39·1 per 1000, the rate during the same period being 18·6 in London and 21·3 in Edinburgh. The 284 deaths registered in Dublin during the week under notice showed a decline of 10 from the high number in the preceding week, and included 46 which were referred to the principal zymotic diseases, against 47 and 57 in the two preceding weeks; of these, 27 resulted from whooping-cough, 7 from measles, 6 from scarlet fever, 4 from diarrhœa, 2 from "fever," and not one either from diphtheria or small-pox. These 46 deaths were equal to an annual rate of 6·9 per 1000, the zymotic death-rate during the same period being 1·7 in London and 2·7 in Edinburgh. The fatal cases of whooping-cough, which had been 19, 27, and 23 in the three preceding weeks, rose again to 27 last week. The deaths referred to measles, which had been 9 and 15 in the two preceding weeks, declined to 7 last week. The 4 fatal cases of scarlet fever exceeded by 2 the number recorded in the preceding week, while the 2 deaths referred to "fever" were below the number in any recent week. The 284 deaths in Dublin last week included 55 of infants under one year of age and 72 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a further increase upon those recorded in recent weeks. Five inquest cases and 11 deaths from violence were registered; and 78, or more than a fourth, of the deaths occurred in public institutions. The causes of 29, or more than 10 per cent., of the deaths in the city last week were not certified.

URBAN MORTALITY IN SCOTLAND IN 1896.

The aggregate mortality from all causes in the eight principal towns of Scotland in 1896 was 28 877, being at the rate of 19·25 per 1000 of the estimated collective population (1,500,435). 11,081, or 38 4 per cent. of the total deaths, were those of children under five years of age. Of the 28,877 deaths, 14,388 occurred in Glasgow, 4680 in Edinburgh, 3105 in Dundee, 2479 in Aberdeen, 1184 in Leith, 1351 in Paisley, 1101 in Greenock, and 589 in Perth. The death-rate per 1000 of estimated population in the respective towns for 1896 was as follows: Glasgow, 20·41; Edinburgh, 16 93; Dundee, 19 21; Aberdeen, 18·24; Leith, 15·98; Paisley, 18·28; Greenock, 17·82; and Perth, 19 36. This is the lowest annual death-rate for the past twenty-one years in Edinburgh, Leith, and Greenock. In Glasgow

Hosted by Google

and Paisley it is the lowest for the past twenty-one years with the exception of 1894. In Aberdeen it is lowest with the exception of 1885. In Dundee, with the exception of three years, it is also the lowest for the past twenty-one years, and in Perth with the exception of four years. Comparing the mean death-rate in the decade 1876–1885 and 1886-1895, we find it was lowered in the latter period in all the eight towns except Leith, where it rose fractionally; but last year, again, Leith had an exceptionally low death-rate. Following the classification of the Registrar-General we find the causes of the 28,877 deaths in 1896 to be as follows:—Specific febrile or zymotic diseases, 4116; parasitic diseases, 8; dietetic diseases, 115; constitutional diseases, 5631; developmental diseases, 1947; local diseases (including those of the nervous, circulatory, respiratory, digestive, and urinary systems), 14,748; violence, 1150; ill-defined and not specified causes, 1162. Generally speaking, the mortality from all causes was under the average for the first six months of the year and over it for the second six months. The highest monthly mortality was in November and December, when the deaths from inflammatory affections of the respiratory organs (not including phthisis or whooping-cough) constituted 26·5 and 24·0 per cent. respectively of the total deaths. As might have been expected from the low general death-rate, the mortality from miasmatic diseases was relatively light last year. From January to May whooping-cough was the most fatal of the epidemics. All the towns except Perth were affected, Glasgow, Aberdeen, and Paisley most markedly so. From that date to the end of the year measles was the most fatal epidemic, Glasgow and Paisley being the chief sufferers. Scarlet fever was also noticeable in August and September in Leith and Paisley. There were no deaths last year from small-pox in any of the eight towns. Roughly speaking, the temperature was higher and the rainfall lower than the average in the first half of last year, and the reverse was the case in the second half.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-MAJOR H. E. R. JAMES, lately returned from Hong-Kong has joined the Army Medical Staff in the Home District, and Surgeon-Major W. G. Clements has joined for duty at Chatham. Surgeon-Major E. A. Roche has taken over Medical Charge of Officers, Women and Children, and the Female Hospital at the Curragh. Surgeon-Major B. T. McCreery has been posted to Dublin for duty. Surgeon-Major J. L. Hall has joined at Woolwich for duty. Surgeon-Major W. Heffernan embarks at Southampton for Bombay. Surgeon-Lieutenant-Colonel William M. James retires on retired pay.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Lieutenant-Colonel Charlesworth, A.M.S., has been transferred from the Mhow District to the Bombay District. Surgeon-Captain Halt, A.M.S., on arrival from England, has been posted to general duty, Bombay District. Surgeon-Lieutenant Morgan, A.M.S., has been posted to general duty, Poona District. Surgeon-Lieutenant Smith has been transferred from the Poona District to the Quetta District. Surgeon-Captain D. G. Marshall (Bengal), is appointed to officiate as Professor of Materia Medica and Pathology in the Lahore Medical College during the absence on furlough of Surgeon-Captain J. Murray, or until further orders. Surgeon-Captain J. Davidson, Bengal Establishment, is appointed to be on special duty in connexion with the famine operations in the Allahabad Division. Surgeon-Captain A. W. T. Buist, officiating Civil Surgeon, is transferred from Ferozepore to Jhelum, relieving Surgeon-Captain J. N. Macleod.

NAVAL MEDICAL SERVICE.

The following appointments are announced: — Staff-Surgeons: D. T. Hoskyn to the *Centurion*, additional, for Yokohama Sick Quarters. J. H. Thomas to the *Orlando*; A. H. Miller to the *Royal Arthur* for voyage home; and F. J. Lilly to the *Mildura*. Surgeons: E. H. McSherry to the *Wallaroo*; F. A. Capps to the *Royal Arthur* on *Waterwitch* paying off; E. C. Cridland to the *Waterwitch*; and H. N. Stephens to the *Centurion*, additional, for the *Esk*.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain James Drummond, M.D., 3rd Durham Volunteer Artillery (Western Division, Royal Artillery), to be Surgeon-Captain.

VOLUNTEER CORPS.

Rifle: 3rd (Cambridgeshire) Volunteer Battalion the Suffolk Regiment: Surgeon-Captain F. P. F. Ransom, M.D., resigns his commission. 4th Volunteer Battalion the Cheshire Regiment: Ralph Bennett Sidebottom, gent., to be Surgeon-Lieutenant. 1st (Cumberland) Volunteer Battalion the Border Regiment: Surgeon-Lieutenant C. W. Graham is appointed Second Lieutenant. 2nd Volunteer Battalion the Durham Light Infantry: Surgeon-Major J. Mitchell to be Surgeon-Lieutenant-Colonel.

THE VICTORIA CROSS.

The following are the names referred to by Dr. Jameson, Director-General of the Army Medical Staff, at the conclusion of his address, reported at p. 366 of our current issue:—Surgeon-Major Thomas Egerton Hale, M.D., V.C.; Assistant Surgeon William Henry Thomas Sylvester, V.C.; Surgeon-General Sir James Mouat, K.C.B., V.C.; Surgeon-General Sir Anthony Dickson Home, K.C.B., V.C.; Surgeon-Lieutenant-Colonel E. B. Hartley; Deputy-Inspector-General of Hospitals Joseph Jee, C.B., V.C.; Surgeon-General Herbert Taylor Reade, C.B., V.C.; Deputy Surgeon-General W. G. N. Manley, C.B., V.C.; Brigade-Surgeon William Temple, M.B., V.C.; Brigade-Surgeon Campbell Millis Douglas, M.D., V.C.; Brigade-Surgeon-Lieutenant-Colonel James Henry Reynolds, V.C.; Surgeon-Major John Crimmin, V.C.; Surgeon-Captain F. S. Le Quesne, V.C.; Surgeon-Major O. E. P. Lloyd, V.C., and Surgeon-Captain H. F. Whitechurch.

Correspondence.

"Audi alteram partem."

"A CENTRAL HOSPITAL BOARD FOR LONDON."

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to give my reasons for moving the amendment (reported in your issue of Jan. 30th) to Sir William Broadbent's resolution regarding the above-named scheme at the meeting of the Council of the Charity Organisation Society on Jan. 25th.

In the first place, I should state that from my experience of the previous meeting of the Council I feared that unless some such amendments were moved there would be little or no attempt made to oppose this scheme. The Charity Organisation Society in its endeavour to obtain a better system of management of the London hospitals is undoubtedly proposing a good work and one which the society is specially fitted to undertake, and from the evidence so far obtainable the scheme of a Central Hospital Board meets with the approval of the general public and of a portion of the medical profession. Is not this, however, probably in great part due to the able advocacy of Mr. Loch and to the invaluable support of Sir William Broadbent? In the draft scheme it is acknowledged that a Central Board of 169 delegates, as proposed, would be a large and unwieldy representative body. Consequently the Executive Committee would do the work, and in time this would pass to an inner ring of men and women who, by giving up their time to it, would hold the reins of power; and what then would become of fair representation?

The Board should have, it is stated, an income of, say, £20,000 per annum, and it is proposed that the Board should make grants to hospitals and dispensaries to facilitate their removal, if requisite, to other districts and to meet other special needs, but no reference is made to the working expenses of this Board. Perhaps it is intended, as suggested by the Select Committee of the House of Lords, that these should be defrayed by levying a small percentage on the income of the hospitals sending delegates. If this Board only obtained an income of £20,000 per annum of what use would that be towards giving grants, as proposed, to institutions whose combined incomes, exclusive of legacies, was in 1892 £600,000 per annum. If, on the other hand, the Central Board scheme were accepted by the public and legacies were

Hosted by Google

left (as suggested) to this board, instead of to individual hospitals, a vast sum of money might in course of years pass into its hands and with this a dangerously controling power which would ruin the individuality of the hospitals, destroy all healthy rivalry, bring them to one dead level, and if wielded by a small clique might sap the foundations of our old and well-deserving charities.

Perhaps I have painted this in too strong colours but surely it is a point worthy of the deepest consideration, and though it is distinctly stated that the Board does not intend to interfere with the hospitals, what will become of intentions when it holds these institutions in a golden grip?

Then, with regard to inspectors, it is stated in the draft scheme that "there is no general system of supervision that insures that defects or abuses are brought to light by inspection and remedied by the common sense of the administration stimulated by the fear of publicity." Such must be the duty of the Board's inspectors "that it may act and report with a competent knowledge of the facts." Surely our great hospitals which have stood some of them the test of centuries do not require the supervision of a Central Board with its inspectors, whose knowledge of their interior economy cannot be so great as that of their own boards. If, however, such inspections were to be made, where are the qualified men and women to be found who would devote their time to this work as volunteers? Paid inspectors would have to be appointed of high probity and special capability, and a serious expenditure incurred thereby.

Lastly, should this Board become all-powerful and dictatorial, personal interest in individual hospitals would be much shaken thereby. Believing, however, that much might be done for the more systematic management of our hospitals, it occurred to me that the Charity Organisation Society could well draw up recommendations to such effect which, after consultation, would meet with the cordial approval of well-constituted hospital committees and render the formation of a Central Hospital Board, with all its attendant expenses, quite unnecessary.

I am, Sirs, yours faithfully,

ARTHUR B. R. MYERS,
Brigade-Surgeon-Lieutenant-Colonel.

Gloucester-street, S.W., Feb. 1st, 1897.

To the Editors of THE LANCET.

SIRS,—I wonder if it has occurred to Mr. Loch and his friends that our hospitals were not built or managed by them, that those who have given largely to the existing hospitals do not often complain of their extravagance or bad management and do not inquire, for instance, how many chickens our sick consume in a year or tell us we have no business to order chickens and such-like dainties to people who are classed as "proper objects" of charity. Perhaps I am wrong, but I never like to ask a person, sick or well, whether he or she is an object. I don't think, however, I have been more often deceived during the last forty years than the best of "organisers," and certainly have seen a few organising friends mistaken in their judgment. But I daresay I am prejudiced against this organising business as regards sick people. Considering that a dose or two of what costs but a small fraction of a halfpenny may give relief in cases of severe pain, I should order the medicine or send the patient to bed without considering in what class of objects he ought to be placed. Few among us, I should think, would like to ask a patient before examining and prescribing whether he had his fee ready, and few of us quite like to put up in large print near the door or in the dining-room—Mr. X's fee is so much, though I have been told by students that, when about to pay for the luxury of going in for a certain examination, before the door was opened wide enough to see anything inside a voice was heard "Hev yer got yer fee?" All this, however, is a matter of opinion, and we don't need to be set right (or wrong) by a Central Board.

Several hundreds of the profession have given their support to the proposal, but probably few have thought how the Board would work. They would give great power to the Board, but has it occurred to them that Central Boards are prone to gain in importance as they get older, and the more power they acquire the more they demand. After a few Board generations, those who worked for the earlier ones as free men become poorly paid servants, and unless they are humble and submissive may soon receive hints that they are not as strong and as capable of work as they were, and stronger persons take their places perhaps at lower wages. In the course of years philanthropy may possibly be changed into a sort of tyranny. I think, too, I have had a hint that some of the smallest hospitals had better be transported elsewhere, while the painful lives led by others are out of kindness to be cut short for the good of the rest. But, when I think of the weakness and powerlessness of many hospital beginnings I have known, extending over years and years when they lived almost upon hope alone, but have nevertheless gained in strength so as to be of the greatest service to large districts, I tremble for the fate of some which are now in that unfortunate condition; but I cannot see why in this country, or on what principle, they should be destroyed. We are all familiar with weak and wretched babes in early infancy and during childhood who grow into strong, useful, and long-lived members of society. I doubt whether several of the youngest and best of our hospitals would in their early years have passed the ordeal of the proposed Central Board in their infancy. I well remember the slow progress of one of the last and best of our hospitals—now admirably placed, arranged, and managed — the Great Northern. I say nothing concerning the early life of my own hospital, but I trust that help will flow direct to University College and that the £15,000 required may be sent to it *direct* before the fifty beds have to be closed and long before the £20,000 a year is paid over to the Central Board to be divided amongst us according to our merits as appraised by that authority that is to be.

I am, Sirs, your obedient servant,

Feb. 4th, 1897. LIONEL S. BEALE.

THE TREATMENT OF MYOMA.

To the Editors of THE LANCET.

SIRS,—The statement made in the columns of THE LANCET of Jan. 23rd that the Gynæcological Society had for three or four years insisted that total extirpation of the uterus was the best treatment for these tumours seems to me somewhat premature, as I do not think that many, if any, cases of this operation had occurred so far back as four years ago in British practice. Those who gave utterance to this sentiment as that of the society form, no doubt, an extremely important section of it; but it is equally certain that an important minority will not give their sanction to any such opinion. I think it probable, for example, that Dr. Bantock and myself could make up a larger list of cases of myoma treated in various ways than all the other members of the Gynæcological Society put together, but neither he nor I have made up our minds as yet definitely on the subject—at least, I can speak for myself. I have tried a number of cases of the so-called "pan-hysterectomy," and have a list much longer than any yet published in England, and I do not find that it commends itself to me in preference to Koeberle's method save in the one particular of being somewhat easier. Indeed, in those cases for which it is adapted I cannot understand how an hour and a half or even an hour can be spent over it unless the proceeding is much interrupted by unnecessary conversation. Its primary mortality, so far as my own work is concerned, is much the same as the clamp operation, but it is too early to speak positively upon this important point. As adverse arguments to the operation there are several points to consider, the first being that there is a distinct group of cases for which it is absolutely inapplicable, and these, unfortunately, are the cases which demand hysterectomy most of all—I mean the soft œdematous myomata. In the tumours having uterine tissue at their base, firm, not given much to shrinking, and with vessels well-defined and separate, the operation can be easily applied.

On Thursday last I operated for one of the former class of tumours and started with the intention of trying the pan-hysterectomy, but found it absolutely impossible. It is, however, upon secondary results that the fate of this operation will depend, and I have seen already enough of them to make me suspect that it will be speedily discarded. The reason is the unfortunate effects of the ligature, a paper on which I published some time ago. In this operation the ligature is not dropped into a peritoneum, which speedily digests and absorbs it, but is pressed among tissue peculiarly apt to resent interference.

Concerning the lower ligatures it must be borne in mind that they are placed with nothing between them and the

Hosted by Google

cavity of the bladder but part of its denuded muscular, and the whole of its mucous coats. These form but a slight protection against a dead ligature finding its way into the bladder. In addition to such an accident as this, three other forms of accident have already passed under my notice—namely, the formation of leakage from a ureter, leakage from the bladder, and leakage from intestine, all incidents occurring long after the primary success had been obtained.

Personally I have been now for twelve years patiently waiting for material upon which I could emphatically express my opinions as to the complete methods and the best of treating myoma, but one thing after another has arisen to alter opinions which I thought had been steadfastly established, and even yet I am obliged to refrain from writing fully on the subject. I think with the knowledge of this that the younger members of the Gynæcological Society will refrain from the positive expressions of opinions which must be premature, and at least they will not pledge the whole society to opinions against which many of their seniors certainly must enter an energetic protest.

I am, Sirs, yours truly,

Newhall-street, Birmingham, Jan. 23rd, 1897. LAWSON TAIT.

P.S.—Should the operation maintain its position in surgery its name ought to be "hysterectomy," as the three derivatives of that word accurately describe it, and I cannot find any classic authority for such a combination as "panhysterectomy"—all classical usages of such a combination are quite different in purpose.

"LIQUID VACCINE VIRUS."

To the Editors of THE LANCET.

SIRS,—With reference to Mr. Kebbell's statement in your issue of Jan. 30th that glycerine was used as a vehicle for vaccine lymph in 1870 I would observe that this is hardly the point in question. That glycerine has been utilised as an addition to vaccine lymph for many years past is surely a matter of common knowledge, but I think that I may lay claim to have been the first to demonstrate the bactericidal properties as regards the "extraneous" micro-organisms commonly present in lymph, upon which the employment of glycerine, after the fashion to which I have called attention, depends for its value. I am not aware that in 1870, or, indeed, prior to the date of my communication to the International Congress of Hygiene in 1891. anyone had called attention to the bacteriological purification of vaccine lymph, which can be brought about by exposing it to the action of glycerine for some considerable length of time before using it for the purpose of vaccination.

I am, Sirs, yours faithfully,

S. MONCKTON COPEMAN.

Cromwell-gardens, W., Feb. 1st, 1897.

To the Editors of THE LANCET.

SIRS,—On referring to an essay I wrote in 1870, when competing for a prize offered by the Medical Council in St. Petersburg, I find therein stated that the most permanent form of preserved vaccine lymph is the crust of vesicles that have run a normal course, and that in using it for vaccinating it should be well moistened with pure water or with *glycerine* and rubbed down on a glass plate, &c. Further, "the vaccine germs and the lymph plasma are *both* necessary for the production of vaccinia."

Since that date I have used and distributed many scores of times a mixture of vaccine and glycerine and noted that glycerine intensifies somewhat the local action of vaccine. Hence, vaccinating with a mixture of vaccine and glycerine is by no means a *new* procedure and can probably be traced to about the commencement of this century. Truly there is nothing new under the sun.—I remain, Sirs, yours truly,

P. MURRAY BRAIDWOOD, M.D. Edin.

Coleshill, Amersham, Bucks, Jan. 30th, 1897.

"THE HALF-YEARLY MEETING OF THE FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND."

To the Editors of THE LANCET.

SIRS,—Mr. Rivington is unnecessarily wrathful with me for having overlooked the fact that in 1885 there was, in addition to the ordinary meeting of Fellows and Members (at which he did not speak), a special meeting on Dec. 17th, at which he made a lengthy oration, which he communicated in advance to a now defunct journal. I apologise for my errors, and with regard to Mr. Rivington's references to the examinership would say that I have been especially careful to make no use of information coming to me officially as a member of the Council; but since Mr. Rivington, "without want of modesty," challenges comparison of his claims to an examinership with those of any who were preferred to him I would point out that he had the opportunity of showing his mettle as an examiner in anatomy and physiology from 1878 to 1883.

I am, Sirs, yours faithfully,

Cavendish-square, Jan. 30th, 1897. CHRISTOPHER HEATH.

*** This correspondence must now cease.—ED. L.

IN MEMORIAM: DR. BALLARD.

To the Editors of THE LANCET.

SIRS,—The friends of Dr. Ballard—and they are "a numerous host"—will be grateful to you for your notice of his character and his work, and, not least, for giving publicity to the photograph of the exquisite portrait of him, painted so happily shortly before his death by his gifted daughter Miss Alice Emmeline Ballard. There is one omission in the obituary which I am sure you will allow me to supply—viz, mention of Dr. Ballard's "report upon the epidemic malady prevalent in Middlesbrough and its neighbourhood, the most obvious character of the disease being pleuro-pneumonia (pleuro-pneumonic fever)." This outbreak was in 1888; and Dr. Ballard's report, occupying some 165 pages of the report of the medical officer of the Local Government Board, constitutes not only one of the most complete accounts of this remarkable disease, but one of the best specimens of Dr. Ballard's work in its painstaking, thorough investigation into every branch and bearing of any subject which he took in hand, full of actual facts and of suggestions for future workers. I am not sorry to have this opportunity of expressing my estimate of a neighbour of whom all Islington practitioners were proud, with whom in his post of health officer he coöperated with perfect harmony and courtesy. It was my good fortune for many years—to him years of trying physical disability—to enjoy his somewhat intimate friendship and to have much intercourse with him. The general impression which will for ever remain with me is that in Dr. Ballard the profession has lost one of its best type of members. Years of sickness are those that try of what sort a man is. No sooner was pain abated than he was at his work again with fresh zest. He never complained, save just a slight regret that he had not "yet completed his diarrhœa report." His interest in the latest literature and the latest science was acute. His honesty of expression was delightful and permitted any criticism. His science, though of the latest, in no way interfered with his devoutness and his faith, as these in no way abated his sympathy with those whose forms of faith might differ from his own. The State has never been better served than by Edward Ballard, and he was a striking instance of the man to whom the duties of preventive medicine are more congenial than those of private practice.

I am, Sirs, your obedient servant,

Highbury-place, N., Feb. 2nd, 1897. JAMES GREY GLOVER.

"THE CASE OF DEW *v.* EDWARDS."

To the Editors of THE LANCET.

SIRS,—In your leading article in THE LANCET of Jan. 30th on this recent case in which I was the plaintiff you say of me, "He appears to have read works on diphtheria, and his view as to the nature of the case was supported by Mr. Lennox Browne, presumably one of the authorities consulted." With all respect I must say that there is no word in my evidence nor anything which occurred at the trial to justify such an inference, nor was any question asked of me on this point either by counsel or his lordship. As a matter of fact, the description of my son's symptoms was given by me within a couple of hours after his death on the evening of Oct. 12th, 1895, to Dr. Williams of Holyhead, who swore, in the course of his examination in Court, that the description which I had then given him of my son's symptoms was precisely the same as the one he had heard me give on oath in the course of my evidence. I

Hosted by Google

had also months before the trial informed my counsel and several medical men of the nature of the symptoms exhibited by my boy during his last illness. I was not aware that Mr. Lennox Browne had ever written any book upon diphtheria until he arrived at Carnarvon to give evidence at the trial, and I never read his book nor any other medical work on diphtheria. The only reference to any volume was to a Homœopathic Handbook of Domestic Medicine a day or two after my son's death to read the treatment and diet there recommended in cases of diphtheria so as to compare it with the treatment, &c., which my son had undergone. The question of calling upon Mr. Lennox Browne as an expert witness was not mooted or decided upon until the night before the date first fixed for trial, nor until I had learnt that similar testimony from distant parts was to be brought forward on behalf of the defendant. Mr. Lennox Browne's book was not even used by my counsel, though it was used by the other side for purposes of cross-examination. Despite the result of the case, it is some satisfaction to me to know that you do not in any way dispute the fact "that cases of malignant diphtheria run a course not dissimilar from that here presented," which certainly appears to justify the evidence of all my medical witnesses, and more especially since you fail to point out any difference between "a malignant sore throat" which is not diphtherial and the one which is.

I am, Sirs, yours obediently,

Bangor, Feb. 2nd, 1897. SAM. R. DEW.

*** In the article referring to the above case in our issue of last week an error was made with reference to the remarks of the judge upon the conversation which helped to mislead the plaintiff as to the nature of his child's illness and the treatment pursued. It was *not* Mr. Lloyd who held this conversation, but as the report states:—"His Lordship said he had not the slightest doubt that the whole thing originated in that statement, an unfortunate one on the part of Mr. David Owen" (referring to the statement that antitoxin had been used in the case). Our error is the more unfortunate as Mr. Lloyd throughout acted with perfect professional propriety under very difficult circumstances.—ED. L.

"THE GLANDULAR FEVER OF CHILDHOOD."

To the Editors of THE LANCET.

SIRS,—In a letter published in THE LANCET of Jan. 23rd commenting upon the paper by Dr. Dawson Williams on Glandular Fever in Childhood I implied that it seemed possible that there might be an epidemic at present in Bristol. Within the two weeks that have elapsed since then I have seen several well-marked cases in the out-patient department of the Children's Hospital showing that there can be little doubt that such an epidemic exists. My object in writing is not, however, mainly to draw attention to this point, but to remark upon the question raised by Dr. Coutts in his letter last week as to the propriety of considering glandular fever a disease of childhood merely. In my former letter I mentioned that I had seen two adults who had suffered, and I have since met with another. A friend told me that the children of a coachman had been seen with their necks tied up. I called and found that all the members of a family of eight children had been attacked a week or two previously with fever and tender swellings in the neck, and in the two children I was able to see the enlarged glands were still present. The main point of interest was, however, that the father, aged forty years, had also suffered, and described the curious difficulty of swallowing that accompanies the disease. Pointing to the cricoid cartilage, he indicated that there was a sense of obstruction in that region which necessitated "a struggle to swallow." Such instances occurring to adults show that although they are evidently less susceptible than children, they may be attacked.

I am, Sirs, yours faithfully,

Clifton, Bristol, Feb. 2nd, 1897. THEODORE FISHER.

SYPHILIS AND HEART DISEASE.

To the Editors of THE LANCET.

SIRS,—Will you allow me to state that the connexion between fibroid disease of the heart and syphilis was first brought before the profession in this country by Dr. Wilks in a communication published in the Transactions of the Pathological Society for 1856? The case was not included in the table of fatal cases in my paper on the subject in THE LANCET of Jan. 23rd, as the cases there tabulated were limited to those in which there were other evidences of syphilis than the heart changes. But I am unwilling that on this account there should be no acknowledgement of the fact that it was Dr. Wilks who first recognised and brought before the profession the effects of syphilis upon the heart wall.

I am, Sirs, yours faithfully,

London, W., Jan. 28th, 1897. SIDNEY PHILLIPS.

"THE VENTILATION OF HOUSE DRAINS."

To the Editors of THE LANCET.

SIRS,—Referring to my letter on the above subject which you kindly printed in THE LANCET of Jan. 16th, p. 208, and which you stated you could not fully answer without further information I beg to give you the following points supplied to me by the surveyor. The depth of the sewers is from 2 ft. 6 in. to 5 ft.; the size of ditto in road from 9 in. to 15 in., the probable distance of same to highest point of house drains, about 30 ft. more or less. The house drains have more than a fall of 1 in 60. The district is a flat one consisting of 244 acres with a population of 5440 and 1088 inhabited houses. Is it possible and *proper* under these conditions to construct ventilating intercepting traps to prevent sewer air entering the house drains and if not what do you suggest with the same object? An answer to this will greatly oblige.—I am, Sirs, your obedient servant,

Feb. 3rd, 1896. BAYNHAM.

*** In view of the details supplied there does not appear to be any insuperable difficulty as to the application of disconnecting traps in the district referred to by our correspondent. The length of house drain mentioned (30 ft.) is short and would indicate narrow streets and small tenements. A house situated under the least favourable conditions given, say 30 ft. from highest point of house drain to highest point of sewer, might be dealt with thus:—

	Ft.	in.
Depth of highest point of house drain below surface of ground measured from bottom of 6 in. drain	1	4
Length of house drain to disconnecting trap, say, 20 ft. with a fall of 1 in 48...	0	5
Drop of drain into trap or fall in disconnecting chamber	0	6
Length of drain from disconnecting trap into sewer 10 ft., with a fall of 1 in 30	0	4
Total	2	7

This, taking the sewer as 9 in. and 2 ft. 6 in. as the depth to the top of the same below the surface of the ground gives a fall to the bottom of the sewer of 3 ft. 3 in., or 7 in. to spare to allow for the difference in the levels of the roads and adjoining properties. Of course this fall of 1 in 30 from trap to sewer will only apply to houses at the extreme end, where the sewers are comparatively empty; lower down, where they run more or less full, the final descent of the house drain must be at an acute angle to prevent backflow, but as the sewer will here be deeper this presents no difficulty. The drains will, of course, be laid upon concrete. 1 in 48 has been given as the fall; 1 in 60 is a fall that requires great care in laying, and if the first can be had it is perhaps better. In London sometimes even a less fall than 1 in 60 is used, but anything between 1 in 30 and 1 in 60 will do; more or less is not desirable. The traps used should have a contracted throat, otherwise they are liable to choke, and the usual inlet and outlet ventilating pipes should be used. All traps should be approved by the surveyor. The second question—as to the desirability of adopting these traps—is perhaps less easily answered. Judging from the population, the acreage, and the size of sewers, the latter,

Hosted by Google

excepting in the matter of ventilation, should, if properly laid, be in fair condition. The daily passage, however, of some 100,000 or 150,000 gallons of sewage, whilst tending to flush a small sewer, must of necessity in its passage through so long a length give off in considerable volume the products of fermentation, though the rainfall on so large an acreage, if passing into the sewer, must be greatly in its favour from a sanitary point. Whilst fixing the disconnecting traps as near to the sewer as possible a certain length of dead drain between the sewer and the trap cannot be avoided, and these dead ends are most objectionable, accumulating the foulest air in the sewer in such close proximity to the houses. Undoubtedly these ends should be fitted with at least a four-inch ventilating pipe on the sewer side of the house trap carried up to a suitable point above the roof of each house, but in this matter discretionary powers should rest with the surveyor who administers the by-law, as in some instances such a pipe might prove a source of danger. To be definite, the disconnecting traps can be used and are certainly desirable as retarding the entrance of sewer air to the inside of the houses, but if used the public drain must be ventilated. Without these traps this is still more a necessity.—ED. L.

"'RETURN' CASES OF SCARLET FEVER."

To the Editors of THE LANCET.

SIRS,—In your annotation in THE LANCET of Jan. 30th under this heading beside the question of neglect at a special hospital comes the more general one of how far persistent desquamation is a sign of infectiousness in convalescents. There is good reason to doubt that the child, aged ten years, was discharged from the hospital while in an infected condition; ragged edges are often found on the hands and feet for some time after infection is over, and cases are not rare where harmless desquamation is continued into the twelfth week or longer. In this case no clue is given as to the time that had elapsed since the commencement of the disease. A similar case is mentioned in this note as discharged after eight weeks in hospital and also a second case, but only a supposition is expressed as to whether one other case may have been due to the first of these, though—"both of these returned children had moved about with perfect freedom among other children at home, at school, or at the Sunday-school." No evidence is forthcoming as to any child having suffered in consequence. Some details of the one case supposed to be originated by the nine-week convalescent would be of interest.—I am, Sirs, yours truly,

WILLIAM SQUIRE, M.D.St.And., F.R.C.P.Lond.

Dunscombe, Ealing, W., Jan. 30th, 1897.

"THE FRINGES OF DISEASE."

To the Editors of THE LANCET.

SIRS,—I have read with great interest Dr. Goodhart's address, published in THE LANCET for Nov. 21st, 1896, on the Fringes of Disease. It brings before us clearly our ignorance of the nature of very common ailments, and should serve as a warning against hiding this ignorance under high-sounding titles, which only tend to confusion. I was struck especially by Dr. Goodhart's remarks on the subject of follicular stomatitis in the adult, for I have very lately had a case of it and must plead guilty to having taken refuge in the stomach theory of causation, although feeling that there was nothing particularly wrong with that much-abused organ.

The facts of the case are these. A woman, aged twenty-six years, confined normally on Aug. 18th, 1896, experienced on the fourth night a species of nightmare which lasted for an hour or so. On the night of the 30th she had similar symptoms, but not so marked, followed in the morning by an attack of vomiting. On examining the heart a loud, musical, systolic murmur of very strange distribution and conduction was heard in the pulmonary region. This murmur, after lasting for a few weeks, gradually disappeared, and at the present date the heart sounds are apparently normal.

The patient did not convalesce properly, a condition ascribed to the heart trouble, which I looked upon as thrombotic, and on Oct. 14th she developed follicular stomatitis (small ulcers with yellowish pellicle). I may remark that at this time the baby was affected with thrush in the mouth. Recurrent attacks in the mother continued until Oct. 23rd, when she left for a change, her mouth being very sore and painful on the day she went away. On the 24th she felt very tired after a night's railway journey. On the 27th she had a pain in one of her knees which almost prevented walking. On the 28th she felt very ill. She experienced a feeling of internal coldness, but no shivering, and her temperature rose to 104° F. On the 29th the temperature was 105°, dropping to normal next day, when dysenteric symptoms began, after which the fever was only slight. The dysentery gradually improved and she was able to get up on Nov. 6th, and though the convalescence was a little slow it was otherwise satisfactory. The stomatitis cleared up during her sharp illness and has not since returned. In connexion with these obscure signs of disease I should like an opinion upon a condition of tongue, of which I have met with one or two cases in young children. I mean a map-like appearance of the dorsum, due to loss of epithelium in patches. What is the immediate cause of this condition?

I am, Sirs, yours faithfully,

WALTER H. HAW, B.A., M.R.C.S. Eng.,
District Surgeon.

Barberton, South African Republic, Dec. 16th, 1896.

THE ELECTION EXPENSES OF DR. J. G. GLOVER, DR. LOVELL DRAGE, AND DR. S. WOODCOCK.

To the Editors of THE LANCET.

SIRS,—It is proposed that subscriptions be raised to defray the expenses incurred in the late election by the candidates, Dr. James Grey Glover, Dr. S. Woodcock, J.P., and Dr. Lovell Drage. Although the two latter were not successful they, considering they appeared for the first time as candidates, made a good fight and will certainly contest the seats again at the next election. The expenses were necessarily heavy, the "constituency" being 24,000 electors. Any sums sent to me will be acknowledged on behalf of the committee and the accounts duly audited.—I am, Sirs, yours faithfully,

A. GEORGE BATEMAN, M.B. Aberd.,
Hon. Sec. to the Election Committee.

49, Devonshire-street, Portland-place, W.

"DR. R. R. RENTOUL AND THE MIDWIVES BILLS."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Jan. 23rd Mr. R. Humphreys gives the lie direct to some of the statements in my address upon the above subject and which appeared in THE LANCET of Jan. 16th. I shall notice only two of his assertions.

First, he takes objection to my having said that the Midwives Bill was a "proposal to hand over confinements, natural and abnormal, to the sole control of the midwife." He says, "No one ever proposed to do such a thing." Although I took care to quote Clause 5 of the first Midwives Bill in my address as published on Jan. 16th, so that supporters of "midwives" registration might be taught the very A, B, C of their proposal, I shall quote it again for their exclusive benefit. Here it is—Clause 5 of the Bill of February, 1890: "A person registered under this Act shall be entitled *to practise midwifery* in any part of England and Wales for gain; and from and after the first day of January, one thousand eight hundred and ninety-one, a person shall not be entitled to recover any fee or charge in any court for the *performance of any midwifery operation*, or for any midwifery *attendance*, or *advice*, unless she be registered under this Act; neither shall she be eligible for any public appointment as a midwife without such registration." (A copy of this Bill can be had from Eyre and Spottiswoode, East Harding-street, E.C.). Now if this clause did not propose to hand over *all* midwifery cases, natural and abnormal, then I fail to understand the meaning of words.

Secondly, I quoted Dr. Matthews Duncan as having stated that 1 woman in every 15 died in her first confinement.

Hosted by Google

Mr. Humphreys asserts that Dr. Duncan "never said anything of the kind." Here again Mr. Humphreys shows his ignorance. If he will refer to Dr. Duncan's work[1] he will find a table showing that 1 in 15 dies in her first confinement, 1 in 8 in the fourteenth confinement, and 1 in 6 in the fifteenth confinement. I am really surprised that even Mr. Humphreys gives himself the congenial part of trying to throw mud at Dr. Duncan. Dr. Duncan was appointed by the Government to report upon this subject, and it is not likely he either wilfully or otherwise told untruths. Had Mr. Humphreys taken the trouble—as the merest tyro would—of having read the statement made by Mr. Stephens, M.P., before the Select Committee upon Midwives Registration (question 586) he would have seen Mr. Stephens stated that the death-rate among women in their *first* confinement at the City of London Lying-in Hospital was 1 in 20; this among 1923 births. Dr. Duncan's figures also are, if anything, too low, because he deliberately excluded all deaths among *unmarried* women—a class who give a very high puerperal death-rate.

If the above are fair samples of my "mis-statements," I think I can leave your readers to judge of their accuracy. If my case is based upon untruths, let it deservedly perish. Will you allow me here to state that the "Editorial Reference Committee" of the *British Medical Journal* has, on Jan. 21st, ordered that my address, which you published on Jan. 16th, is to be suppressed from the journal? This "Reference Committee" consists of Dr. H. Barnes (Carlisle), Dr. Roddick (Montreal), Dr. C. Parsons (Dover), Dr. T. Bridgwater (Harrow), Dr. J. W. Cousins (Southsea), and Dr. C. Holman (London). Why have they thought it worthy of being suppressed? May I ask as a favour, through THE LANCET, that each practitioner interested in this vital question order at once 100 reprints of my address, so that he may send it to M.P.'s, county councillors, boards of guardians, and members of medical societies?

I am, Sirs, yours truly,

ROBERT R. RENTOUL,

Liverpool. Direct Representative, General Medical Council.

"POISONING BY ANTIPYRIN; RECOVERY."

To the Editors of THE LANCET.

SIRS,—The case of poisoning by antipyrin recorded by Mr. Webster in THE LANCET of Jan. 30th reminds me of a case I saw a few years ago in Calcutta. The patient was a middle-aged woman, convalescent from typho-malarial fever. She was suffering from severe headache, for which I gave her ten grains of antipyrin, with twenty minims of spiritus ammoniæ aromaticus and an ounce of water. In about half an hour's time the patient's condition much resembled that described by Mr. Webster, but with these differences: she was very pale, not cyanotic; there was no swelling of the eyelids, but almost complete loss of sight, and the rash disappeared in about eighteen hours. It much resembled that of urticaria, but there were no small papules, as in Mr. Webster's case. It is interesting to note that the rash in cases of chronic antipyrin poisoning is small scattered papules only, which are seen chiefly on the flexor surfaces. My patient rallied well on the administration of hot coffee and whisky. I am, Sirs, yours faithfully,

FRANK G. WALLACE, M.A., M.B., B.C. Cantab.

Earl's-court, Feb. 1st, 1897.

CHRONIC ULCERATION TREATED BY OXYGEN.

To the Editors of THE LANCET.

SIRS,—Will you permit me to make a correction in your kind report in THE LANCET of Jan. 30th of my oxygen cases shown at the Clinical Society? *All* the final bacteriological examinations showed only *staphylococci*, all the other micro-organisms having disappeared. I have obtained identical results in hundreds of examinations. I mentioned these facts to show the selective power that oxygen undoubtedly has.

I remain, yours faithfully,

Hertford-street, Mayfair, W., Feb. 1st, 1897. GEORGE STOKER.

[1] Mortality of Childbed and Maternity Hospitals, p. 41, table vi.

MALE NURSES.

To the Editors of THE LANCET.

SIRS,—It is possible that some of your readers may be inconvenienced by an erroneous statement of Lady Priestley in the *Nineteenth Century*. Having mentioned the necessity and propriety of employing male nurses in certain cases Lady Priestley regrets that there should be no institution for supplying them. This is an amazing misstatement considering that the Hamilton Association for providing male nurses was founded in May, 1885, and has been steadily at work up to the present time. Many medical men have employed the nurses under the association, and have testified to their ability and attention. During all this time the association has been regularly advertised in the THE LANCET, and on more than one occasion you have expressed your editorial approval of its work; even as early as 1886 you pronounced it "deserving of support." Let us again remind your readers that the Hamilton Association is not a commercial, but a philanthropic institution. Its object is not to make a pecuniary profit, but to be a benefit to both patients and nurses, and therefore to medical men. Thus it differs altogether from proprietary concerns which since its establishment have added this branch to their business. It is managed by a committee on which the profession is fully represented and which is therefore able to exercise needful discipline. Admission to the roll of the association is only obtainable after full inquiry into the character and antecedents of candidates and is the best guarantee the public have of the qualificatiions of a nurse. You will, no doubt, remember that the association was founded by the late Miss Jane Hamilton, a lady whose relatives were hospital physicians and surgeons. Miss Hamilton had seen the necessity of men being trained as nurses to attend to various cases, had witnessed distress at the difficulty of obtaining them, and founded the association at very great expense, leaving a legacy at her death to carry it on. Surely Lady Priestley should have known this before writing on the subject. We hope, however, the publication of these facts in your columns may go far to neutralise the injurious effects of her misstatement.

We are, Sirs, yours faithfully,

THE TREASURERS OF THE HAMILTON ASSOCIATION.

Park-street, Grosvenor-square, W.

*** "The Hamilton Association for providing trained male nurses is one deserving of support. It is most desirable, we think, that male nurses should be employed for attendance on the sick of their own sex whenever practicable." These were our words concerning the Hamilton Association in THE LANCET of Aug. 7th, 1886, and they convey our opinion at the present time.—ED.L.

"ARMY EXAMINATIONS."

To the Editors of THE LANCET.

SIRS,—May I say, in answer to "Uncrammed," that I did not uphold the current scheme of "Army Examinations," neither did I decry our public school life, and I certainly do not call in question the capacities of the school teachers? My point is that the inevitable competition, whatever the subjects of examination may be, is the great cause of the parental complainings, with which everyone must sympathise. This competition means that only a proportion of candidates can be successful, notwithstanding that all may come up to a satisfactory standard of physique, mental equipment, &c., and have enjoyed the advantages of a public school training. But the misfortune is that this is not enough. These candidates have to compete with one another, and the competition necessitates a special preparation which is carried out under disadvantages at school, but, for reasons I gave, with more success outside by special army instructors. The need of this special preparation may be deplorable, but how is "Uncrammed" going to obviate it? To eliminate competition is impossible, and the only other way to suppress these outside army instructors is for the schoolmasters to be more successful. Even then, does "Uncrammed" suppose there would be no distressed parents left to write to the papers and bemoan their hard lot? Are the lads who cannot compete successfully from school to give up the struggle? But what harm do these army instructors do? THE LANCET, having

Hosted by Google

branded them as "crammers," denounced the short sojourn with them as pernicious to a candidate's mind, body, and estate, and pointed out their costliness as a bar to the competition of a poor man. Candidates for the army, be it noted, with few exceptions have enjoyed a costly public school training. I disputed THE LANCET'S conclusions with regard to the "crammers," and there is no need to repeat my remarks.

I am, Sirs, yours faithfully,

Feb. 1st, 1897. PHYSICIAN.

HOSPITAL ABUSE.

(BY OUR SPECIAL COMMISSIONER.)

VI.—LEEDS.[1]

Extensive Abuse at the Leeds Infirmary.—The General Practitioner's Grievance.—Result of a Small Plébiscite on Hospital Abuse.

IT is very generally acknowledged that considerable abuse prevails at the Leeds Infirmary. Considering the importance of this institution this fact has a very marked effect upon the profession generally. The Leeds Infirmary was first established 129 years ago and now ranks among the largest and finest hospitals in the kingdom. In 1894 there were 48,715 old and new patients treated at the Leeds Infirmary, of whom 6115 were in-patients. The accidents alone amounted to 8138 and among these 966 had been admitted as in-patients. The cases were so severe that 111 died within forty-eight hours. The total number of new patients amounted to 41,093 in 1894 and to 42.976 in 1895, and the population of Leeds is estimated at 367,505. These figures suffice to show what a very large proportion of the sick resort to the infirmary, and out of so great a number there must be many cases of abuse. This was not denied. Indeed, one of the principal surgeons on the infirmary staff acknowledged that according to the general impression there is abuse. He remembered that some years ago a member of the Charity Organisation Society was engaged, and he made a list of patients who lived in good locaiities or appeared to be in good circumstances. These persons were visited at their own homes, and the result of the investigation proved that there were many cases of abuse. But the question was now gravely complicated by the large contributions given by the workpeople, who were every year assuming more and more authority in the control of the hospital. Another leading member of the hospital staff thought the infirmary should only be open to patients sent by a medical man for consultation, except in cases of accidents or emergencies. It was little use complaining about "sixpenny doctors" while the infirmary continued to compete with the medical profession. Fortunately, Leeds was in the happy position of not possessing too many charities, and therefore the charities, if they competed with the profession, at least did not compete with each other. This happy condition of affairs could not, however, last. The infirmary had reached the maximum limit of possible extension. As the town continued to grow rival hospitals would certainly be started, and then the difficulty of dealing with the question of abuse would be greatly aggravated.

A third member of the infirmary honorary staff related to me that a country medical man had sent to him a patient suffering from a wound of the head. After attending to this patient once or twice at his surgery he found him among the out-patients of the infirmary, where he had been admitted though he possessed ample means. Another out-patient, who came to be treated for stricture, was known to be in receipt of a weekly income of £4 and to have boasted that he spent £2 a week in drink. Why should men who can spend £2 a week in drink avail themselves of a charity intended only for the poor? Another patient, a woman who had a slight operation performed, made a donation of £4 4*s.* to the infirmary on leaving. This person could very well have afforded to pay the usual fee. That she gave a donation to the infirmary is satisfactory in itself, but this does not help to relieve the economic pressure on the medical profession caused by the competition of hospitals. The casualty department of the infirmary was also much abused because people rushed to the infirmary instead of going to their local practitioners. This was notably the case with regard to accidents that occurred at football matches. If a youth or man had money enough to devote himself to football and regularly engaged in matches he should have money enough to pay for ordinary surgical attendance and should only be admitted into the hospital when the injury was so serious as to necessitate a treatment so lengthy and expensive as to be altogether beyond his means. The greatest abuse related to the trivial cases. It is true that they occasioned such a slight expense that it would probably cost more to organise a system of prevention than to allow the evil to continue. But this swamps the out-patient department, and it is bad for the education of the medical students, as so large a number of cases have to be hurried through. If these trivial cases could be excluded the medical men would have many more private patients. Among the male out-patients the trivial cases were not so numerous as in the case of the female. Men often could not afford the time to wait an hour or two before getting the advice and medicine they needed, but with most women and children time was no object. The visiting surgeon or physician would find himself quite exhausted by the time he had sifted and disposed of these trivial cases, and when he came to the interesting cases where useful demonstrations could be given to the students he was already fatigued and scarcely fit for the task. This grievance became so urgent that measures had to be taken, and now the residential staff go the round of the waiting-rooms and sift the patients, thus relieving the visiting staff of many of the trivial cases. There was no denying that there was abuse—great abuse—my informant concluding by saying that he constantly saw at the hospital patients who not only could pay a half-crown, but even a guinea fee.

Speaking to a general practitioner who had been for some years residential surgeon at the infirmary, he expressed opinions very similar to those uttered in my presence by various members of the Manchester Medical Guild. He explained that he was particularly interested in surgery, but that, to his great disappointment, he found there was no surgery left for the general practitioner. He had been in general practice for several years and he had had only three surgical cases. Even for the smallest accident people now all went to the infirmary. The surgical education now enforced was quite useless, and it sufficed to be in general practice for a few years to forget to a great extent what had been learnt. It was absolute waste of money to buy surgical instruments; they would rust for want of use, and the fees were so few that they would never cover the cost. The general practitioner could not compete in surgery with the hospital—he must content himself with medical cases, and these for the most part trivial cases. When the illness was more serious then the class of patients who could only afford small fees had a fair excuse for going to the hospital. Thus among his patients he found that a man who might be considered a well-to-do tradesman, went to the infirmary because he had a sore finger. Another tradesman, who owns the house in which he lives, also tried to get advice at the infirmary, but this case was detected and refused. Close at hand, however, a shopkeeper goes every week to the infirmary for atropine drops, although he is able to pay the ordinary fees for medical attendance on his wife and children. He knew of persons in receipt of £4 a week who went into the infirmary for every little ailment, even to have a tooth drawn. Further, they reproached their neighbours, and called them extravagant and "stuck up" if they did not also go to the infirmary. He thought that the staff at the infirmary were not keenly alive to the necessity of reducing the number of patients.

Mr. W. H. Brown, one of the surgeons of the infirmary staff, some time ago sent a circular to a hundred general practitioners established at Leeds. In this circular he asked four questions. First, whether they thought that there was abuse at the infirmary, and, if so, whether it was among the in-patients or the out-patients? Secondly, whether the infirmary injured their private practice? Thirdly, whether there was any advantage to counterbalance the injury done, such as the convenience of being able to get rid of troublesome patients or of cases where expensive appliances

[1] The previous articles on this subject were published in THE LANCET on the following dates: (1) Sept. 26th, 1896, Plymouth and Devonport; (2) Oct. 10th, 1896, Exeter; (2 *continued*) Oct. 17th, 1896, Exeter; (3) Oct. 31st, 1896, St. Thomas's Hospital, London; (4) Nov. 14th, 1896, Liverpool; (4 *continued*) Nov. 21st, 1896, Liverpool; (4 *continued*) Dec. 12th, 1896, Liverpool; (5) Jan. 2nd, 1897, Manchester; (5 *continued*) Jan. 9th, 1897, Manchester; and (5 *concluded*) Jan. 23rd, 1897, Manchester.

Hosted by Google

were required? Fourthly, whether they could make any suggestions to lessen the abuse? Over ninety replies were received. Without exception all agreed that there were abuses and that these were more frequent in the special departments. The majority said that the competition of the infirmary did injure them financially, but that this injury was compensated in a great measure, if not entirely, by the convenience afforded in being able to transfer costly or troublesome cases to the infirmary. Many general practitioners in their replies made a point of the fact that they experienced no difficulty in getting their private patients admitted to the infirmary. There were not many suggestions as to likely remedies. Most of these suggestions embraced proposals for the establishment of a wage limit, and one medical man went so far as to urge the total abolition of the infirmary. On the strength of these replies Mr. Brown propounded a plan according to which a printed form was to be given to every out-patient who appeared to be in a superior position. He would then receive medical advice and medicine sufficient for two days, but would not receive further advice or medicine unless he brought back the form signed by a magistrate, a minister of religion, or a medical man. This form consists of a certificate setting forth that the applicant "is a proper person to be under the infirmary treatment." This scheme was not adopted, nor does it seem to offer a satisfactory solution of the problem, for it leaves to the signatories of the certificate the responsibility of deciding who are suitable recipients of such charity. Some would be very lenient and others very severe; there would be no uniformity. Mr. Brown explained that he performed many operations on patients at the infirmary who could afford to pay moderate fees for ordinary illnesses. For instance, he had for that day an operation of ovariotomy on a woman whose husband was earning twenty-eight shillings a week. Though she lived in a very nice little cottage, still it was not a proper place for such an operation; the medical man, therefore, who attended this patient himself asked to have the case removed to the infirmary. Such cases surely ought not to be refused.

(To be continued.)

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The New General Hospital.

THE arrangements towards the completion and opening of a new general hospital are rapidly approaching settlement. The Queen has deputed Princess Christian to represent her at the opening ceremony, which is expected to take place in June. It is anticipated that the occasion will be made the opportunity for an appeal for further funds, of which some £40,000 are yet wanted. Mr. J. C. Holder, the chairman of the committee, has promised an additional £5000, a noble example of generosity. A fitting and useful mode of obtaining subscriptions is by the endowment of individual beds. For this purpose the sum of £1250 set apart for each bed so endowed. Already advantage has been taken of this in a number of instances, where the name of a particular donor or the memory of some deceased is perpetuated by a name affixed to the bed so set apart. On all sides there is nothing but admiration for the structure and a justifiable pride in the addition to the city of this monument of philanthropy and benevolence.

Medical Defence.

An elaborate report drawn up by a committee of the Birmingham and Midland Counties Branch of the British Medical Association and presented at the last ordinary meeting was rejected by 21 votes to 18. The tendency of opinion was that the Association should keep free from this particular question, which it was considered would be best carried out by a separate and independent organisation.

The Arrest of Tuberculosis.

An address upon this subject was given before the Warwickshire Chamber of Agriculture on Jan. 30th by Sir James Sawyer. Stress was laid upon the fact of prevention being better than cure; and after a lucid description of the tubercle bacillus and the principal modes of prevention of its spread measures were considered for combating the disease and spreading the necessary knowledge for understanding the subject by the light of modern investigations. The following resolution was passed: "That this Chamber recommends that the facts of tuberculous disease should be diffused among agriculturists, together with the plain common-sense measures for its prevention that may suggest themselves; meanwhile, that agriculturists should await further enlightenment from scientists who are investigating the subject."

The City Council and the Drainage Board.

A recent resolution of the City Council instructed the General Purposes Committee in the following terms: "To consider and report whether any, and if so what, means can be adopted by the council to obtain a greater control over the acts and expenditure of the drainage board than exists under the present system." The committee has issued a report in which it is stated that the City Council have legally no controlling power over the drainage board other than such as may be exerciseable by the fourteen representatives appointed by the City Council who are a majority of the board. Any attempt they consider to exercise this would be impolitic and unwise in the face of the existing authorities who constitute the board.

Feb. 3rd.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manchester Royal Eye Hospital.

AT the annual meeting of the Manchester Royal Eye Hospital, last week, it was stated in the report that the number of out-patients last year had been 22,364, an increase of 1,656, as compared with the previous year; 10,276 attending at Oxford-street, and 12,088 at St. John-street. The number of in-patients admitted was 1,370, an increase of seven. 3,825 accidents were treated at the two hospitals. The arrangement adopted in 1894 of appointing two house-surgeons so that greater attention might be given to the out-patients, has been continued, and found advantageous in every way, and the "board of management have much pleasure in acknowledging the valuable services which both gentlemen—Dr. J. G. Clegg and Dr. J. A. Menzies, have rendered to the hospital." The re-arrangement and furnishing of rooms at Oxford-street, where it was thought advisable for them to be quartered, as well as the installation of the electric light in some parts of the hospital, with other necessary work, have involved a considerable addition to the expenses. Notwithstanding this "the finances of the hospital continue in a very satisfactory condition," a statement not often made in a hospital report. A remark in the speech of Mr. David Bannerman, the chairman of the board, may be noted as illustrating a very common feeling among the supporters of hospitals. In paying a well deserved tribute to the memory of the late hon. secretary to the hospital, who for twenty-three years had acted in that capacity, he said: "Joining the board when the number of its patients was less than 3000 and its income less than £1000, Mr. Parlane watched and contributed to its growth and development until its numbers had risen to over 22,000 and its income to more than £4300." There is the usual feeling of exultation at the great increase in the number of patients, no doubt naturally enough, for everyone likes success, but there is no indication that the question of hospital abuse had suggested itself. There are plenty of poor deserving cases and no doubt far too many pitiful ones to whom the hospital is rightly an invaluable boon, but how many of the 23,364 out-patients had trivial ailments that could have been dealt with by the general practitioner, and how many of them could easily have paid his modest fees?

Fatal Boiler Explosion.

Your warning as to the danger of kitchen-boiler explosions, given in THE LANCET of Jan. 30th, has been unhappily illustrated at Ramsbottom. At an inquest held last Thursday respecting the deaths of two little girls of seven and five years of age, it appears that they were killed through the bursting of a self-feeding kitchen boiler on the previous Tuesday. The evidence was to the effect that, "owing to the severe frost, the water in the outlet pipe of the hot-water apparatus had become frozen, with the result that the kitchen boiler burst, and, in addition to partly wrecking the house, severely injured a man named Tycroft, his wife, and four children, two of

Hosted by Google

whom died in the Ramsbottom Cottage Hospital." The boiler was said to be thicker than those usually fitted in cottage houses, which only shows how useless the increase of thickness is when no safety-valve is provided. A death was recorded about ten days ago, due indirectly to the cold weather, showing the danger of hot-water bottles. A little girl, aged eight years, named Ashworth, of Middleton, was scalded on the Monday and died on the Wednesday. At the inquest it was stated that the mother put three children in the same bed and afterwards put in a hot-water bottle. She had no sooner done so than the bottle, which had been warmed in the kitchen oven, burst, the cork being forced out by the steam. The three children were badly scalded, and one, who was very much injured about the lower part of the body and legs, died as above stated. "The jury were of opinion that death was due to accidental causes," and not, it is to be supposed, to the natural consequences of ignorance or thoughtlessness. This is tragedy, but it is not far removed as to cause from "an accident," which—fortunately, as it happened—may be looked upon as comedy. The stopper of a decanter having stuck the lady of the house directed it to be taken to the wash-house and put into the boiler, which was done. Shortly after a loud explosion was heard, and on some one going to see what had happened the remains of the decanter were found in innumerable fragments, so that this mode of extracting stoppers was given up. Happily no one was present when the explosion occurred.

Salford and the Queen's Commemoration.

Salford has decided to commemorate the sixtieth year of the Queen's reign by establishing a central nurses' home in connexion with the Manchester and Salford Sick Poor and Private Nursing Institute, which is already affiliated with the Queen Victoria Sick Poor Nurses' Home. An appeal will be made to all classes in Salford for contributions towards raising a fund of not less than £10,000 to cover the cost of the requisite land, the buildings, and their necessary equipment. At the public meeting yesterday about £1450 were promised by some of the gentlemen present.

Intoxicants in Stockport Workhouse.

A discussion took place at the meeting of the Stockport board of guardians yesterday respecting the taking of beer and spirits into the workhouse by the officers. Dr. Rayner said that this abuse of stimulants had led to the abuse of decency and to several officers being dismissed. One officer gave drink to a pauper with the result that the latter was sent to gaol for drunkenness. The board ordered that in future no spirituous liquors are to be taken into the workhouse without the written consent of the master.

Royal Infirmary.

The plans of the ten architects who were selected to compete for the design of the new infirmary on the present site have been (by the kind permission of the Lord Mayor) publicly exhibited in the Lord Mayor's parlour at the Town Hall during the past week between the hours of 9 A.M. and 5 P.M.

Feb. 2nd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Edinburgh Medical Missionary Society.

THE annual meeting of this society was held last week, the President, Sir T. Grainger Stewart, presiding. Dr. Fry, the superintendent, intimated in his report that during the year 10,243 new cases had been treated at Cowgate Dispensary. As regards the finances of the society they showed an excess of expenditure over income of £352. A number of missionaries spoke and testified to the value of medical knowledge by missionaries and the great advantages of medical missions.

The Association for the Better Endowment of the University of Edinburgh.

The report for the past year shows that this association continues to do a useful if quiet and unobtrusive work in connexion with the University. The most outstanding feature is a bequest of £1500, in memory of the late Dr. John Allan, H.E.I.C.S., left by his widow for a medical scholarship on conditions that the sum be increased to £2500 within two years. The association necessarily see difficulties in finding this extra £1000, although they are anxious to be able to utilise the bequest.

Various Medical Institutions in Edinburgh.

The Royal Public Dispensary, the Eye, Ear, and Throat Infirmary, and the Dental Hospital and School have all held their annual meetings and submitted their annual reports, from which it is seen that they respectively continue to perform their parts in the medical teaching and amongst the medical charities of Edinburgh.

Scottish Poor-law Medical Officers' Association.

The second annual dinner of this association was held in Glasgow on the 27th ult. The chair was taken by Mr. Alex. Cross, M.P., who, in proposing the toast of the association, remarked upon the large number of medical men in Scotland—some 800—who were officers concerned with the operation of the Poor-laws, and said he had no doubt that all of these, when the objects of the association were better understood, would become members of it. He recognised a substantial grievance in the position of the medical officers in relation to the parish councils which had the power to dismiss the medical officers without right of appeal. This should undoubtedly be remedied by granting to every medical officer a power of appeal to the central authorities. At present the question of a superannuation allowance was probably premature, but recent legislation with regard to the English officials would give to a Scottish demand considerable force. Mr. W. L Muir, president of the association, replied, and in doing so disclaimed any antagonism on the part of the medical officers to the parish councils, but contended that it could not be held that the service was free from grievances, and it was their object to secure the removal of these grievances.

Royal Hospital for Sick Children, Glasgow.

The annual meeting of subscribers was held on Jan. 26th, the chair being taken by Lord Provost Richmond. The report showed a considerable increase in the number of cases treated in the hospital, more especially in the surgical wards, but the financial statement indicated a deficit of no less a sum than £1553 11*s.* 1*d.* in the year's working. Dr. Hector C. Cameron, in supporting the motion for the adoption of the report, referred to the form in which hospital reports were issued as appealing to the public apparently on the grounds of minimum cost per patient and per bed and minimum period of residence. He questioned whether this condition was an ideal to be desired, and would almost rather see a board of directors boasting of the large expenditure of money on each patient and a prolonged average period of residence. In this direction rather than in the opposite one he looked for the measure of the usefulness of a medical or surgical institution. Dr. Cameron had no doubt that a hospital for sick children was an admirable and even a necessary charity, though he was by no means inclined to view without concern the indefinite multiplication of medical charities. Many of the so-called special hospitals were not only unnecessary, but had, in addition, the unfortunate effect of diverting subscriptions from institutions the necessity for the existence of which was beyond dispute.

Medical Appointments and Vacancies.

Mr. Francis J. Barber, M.B., C.M. Glasg., and Mr. Frank Hill, M.B., C.M. Glasg., have been appointed to be House Surgeons to the Glasgow Eye Infirmary. Mr. Robert Cormack, B.Sc., has been elected Professor of Botany in Anderson's College Medical School. Mr. Alfred Young, M.A., M.B. Glasg., has resigned his position as Surgeon to the Glasgow Central Dispensary. The appointments as in-door and out-door House Surgeons to the Glasgow Maternity Hospital are intimated to be vacant.

Faculty of Physicians and Surgeons of Glasgow.

Mr. John H. Chaldecott, L.R.C.P. Lond., having passed the necessary examinations and been elected, has been enrolled a Fellow of the Faculty.

AT a meeting of the Dublin Corporation held on Feb. 1st the Lord Mayor called the attention of the Council to the

Hosted by Google

fact that the War Office authorities had now declined to give over possession of the Pigeon House Fort, and had only agreed to give over a portion of it on payment of £20,000. He further observed that, inasmuch as the Corporation were not likely to get the buildings into their hands for two or three years, the Council must now face the situation and deal with the important matter of an Isolation Hospital with as little delay as possible. He believed that there were thousands of people in Ireland who would subscribe towards the establishment of such a hospital outside the city, and be ready to signalise the sixtieth year of the reign of Her Majesty by a generous response for such a purpose.

Poisoning by Coal Gas at Drogheda.

A lodging-house in Drogheda was, on account of information received, forcibly entered by the police on Sunday morning. The three bedrooms, which were filled with gas, were found to contain eight men, all in a state of insensibility. After the use of various remedies the medical men in attendance succeeded in restoring five of the inmates to consciousness, two of the eight being already dead. The remaining man is now conscious, but lies at the Union Hospital in a precarious condition. It is alleged that a heavy traction engine which passed through the narrow street in which the house is situated on Friday night may have caused a break in the gas main. The inquest has been adjourned in order to allow a thorough investigation into the matter.

Annual Meeting of the Dublin Branch of the British Medical Association.

The annual meeting of the Dublin Branch of the British Medical Association took place at the Royal College of Physicans of Ireland on the 30th ult., when an address was delivered by Dr. Wallace Beatty advocating the Systematic Teaching of Dermatology in the Medical Schools.

The Samaritan Hospital for Women, Belfast.

At the annual meeting, held on Jan. 28th, the medical report stated that during the year there had been 721 new extern and 203 new intern cases, and 158 operations were performed. In both departments there was an increase in the number of patients. Twenty-four abdominal operations were performed. A generous gift of £500 from Mr. Forster Green has enabled the committee to proceed with the erection of a new wing for cases of cancer, and this is nearly completed. The household expenditure, including medicines, amounted to £388 13*s.*, while the contributions from intern patients were £340 12*s.* 6*d.* A hearty vote of thanks was accorded Mr. Green for his generous contribution.

The Belfast Hospital for Sick Children.

At the annual meeting, held on Jan. 29th, it was reported that during the year 1896, 293 children were admitted into the wards, and of these 129 were surgical, 154 medical, and the others eye and ear cases; 127 operations were performed with four deaths. In the extern department there were 9494 cases. A large class of students are attending the hospital. Financially the receipts were £500 more than the previous year, still the expenditure exceeded the income by £194, the total expenditure being £1868, but the average cost has only been 12*s.* 4*d.* per head weekly.

The New Infectious Diseases Hospital for Belfast.

A deputation from the North of Ireland Branch of the British Medical Association waited on the Public Health Committee of the Belfast Corporation on Jan. 28th, urging that, in accordance with a resolution passed at the last meeting of the branch, the infectious diseases hospital should not be built at Purdysburn on the grounds that the conveyance of patients such a distance would militate against their recovery, and that for the convenience of students, for whom a knowledge of such diseases was essential, such a hospital should be nearer the city. The deputation were most cordially received, and the matter is still under consideration, but there is no doubt the site at the asylum in Grosvenor-street would be in every respect the most suitable.

Prevalence of Influenza in the North of Ireland.

At the present time there is a widespread epidemic of influenza throughout the north of Ireland, and in some districts—Coleraine, Garvagh, and Cookstown—the type of the disease has been severe with considerable mortality. In Belfast during the past month many cases have occurred, and in that city, while the epidemic of scarlet fever is subsiding, there are many cases of measles.

The Cork District Lunatic Asylum.

Dr. Oscar Woods, resident medical superintendent, submitted his annual report at the last meeting of the governors of the Cork Asylum. The figures showed a great increase in the number remaining under treatment and the admissions were considerably above the average. With regard to heredity, Dr. Woods points out that in 32 per cent. of those admitted during the year there was a distinct hereditary predisposition. This he considers a very high percentage, as the average in England for the past five years has been only 23 per cent., and in American asylums it is as low as 10 per cent.

Mr. P. A. McDermott, F.R.C.S. Irel., has just been appointed to the Visiting Staff of St. Michael's Hospital, Kingstown.

Feb. 2nd.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

France and the Bubonic Plague.

IN the medical world the subject of bubonic plague occupies all our attention. Professor Proust, Inspecteur en Chef des Services Sanitaires, has made a long report to the Academy of Medicine, in which he records statistics in illustration of the unchecked progress of the epidemic from Hong-Kong to Bombay, and from Bombay to the Red Sea. He drew from his report the conclusion that if the resolutions passed at the International Sanitary Conference of Paris in 1894 had been accepted with unanimity by the European Powers Europe would be to-day completely protected against the plague. He pointed out the danger of the invasion of the Continent from the Persian Gulf, where no proper surveillance had been organised, and declared that it was absolutely necessary that the Mecca pilgrimage for next spring should be interdicted or, failing that, that the strictest sanitary precautions should be taken with regard to it. France had arranged for these precautions in connexion with her Mussulman subjects in Algeria, Tunis, and Senegal, and Professor Proust hoped that England would do the same. "Si chacun fait son devoir," he concluded, "l'Europe sera à l'abri du fléau." Government has now taken every means to enforce the decree of Jan. 4th, 1896, by proscribing under the severest penalties the introduction into France of any merchandise directly or indirectly coming from Bombay or from a known infected source, save by the ports provided with a *lazaret* such as Marseilles, Pauillac, St. Nazaire, Havre, Dunkirk, and Algiers. The decision of the English Government interdicting the departure of pilgrims from Bombay and Karachi and supporting the scheme for an international congress at Venice was received with great pleasure in France. MM. Brouardel, Proust, and Barrère have been chosen to represent France at the Congress, the sittings of which will commence on Wednesday next, Feb. 10th.

The Bacillus of the Plague.

Professor Roux, Director of the Institut Pasteur, has made a communication to the Academy of Medicine upon the bacillus and serum pathology of the bubonic plague. He described the work of Dr. Yersin and the characteristics of the bacillus, and dwelt upon its probable dissemination by rats and mice, or from the expectorations, stools, and even the blood of the patients. He also alluded to Dr. Yersin's experiments in "vaccination" against the plague and the successful cases reported from Canton and Amoy. He considered it established that the protective serum could be kept unaltered in spite of weather and travel, and that it was efficacious when employed at the commencement of the malady. There was nothing new in Professor Roux's dissertation, which was obviously made not so much to inform the scientific world as to re-assure laymen.

Anti-typhoid Serum.

In the learned societies two important contributions have lately been made to the study of typhoid fever. M. Chantemesse has communicated to the Société de Biologie the discovery of a simple toxin extracted from cultures of the typhoid bacillus. It is obtained most readily by cultivating

Hosted by Google

the bacillus in bone marrow or the pulp of spleen macerated at a low temperature. It is more resistant to warmth than to cold and can only be preserved by exclusion of air and light. Curiously enough, according to M. Chantemesse, its toxic power is more marked among large than small animals. He is now making inoculation experiments upon horses at the Institut Pasteur, and we may expect the records of his results. At the Société Médicale des Hôpitaux M. Ferrand and his assistant gave an account of a singular case of apparent typhoid fever in which the serum reactions of M. Widal had been obtained when the patient was in reality not suffering from typhoid fever, but from septicæmia the result of an injury to his finger. M. Widal, who was present at the meeting of the society, criticised the method employed by the experimenters in the case.

Le Service Médical de Nuit.

This service continues to occupy the attention both of medical men and the Municipal Council. During ten years it has rendered the greatest service to the community, for anyone taken ill during the night was able to obtain from the police station the help of one of the medical men enrolled for the service. A medical man summoned in this way was paid ten francs by the municipal administration, who recovered the same from the invalid, save in the case of paupers. The Municipal Council has, as your readers well know,[1] found the strain upon their finances too great. Repayments were infrequent, and from economical motives the Council decided that each medical officer of the service should be paid a salary of five hundred francs a year, irrespectively of the number of visits that he might be called upon to pay. Most of the medical men refused to accept the terms and Paris is now without its *service médical de nuit*. The trouble has arisen from the fact that the conditions of the service varied much according to the social status of the residents in the different districts. In rich districts the medical man would expect to be disturbed say twice a month, but in poor districts he might have to rise six times in the night, so that to award the same payment all round was to inflict an obvious injustice. Negotiations are still proceeding between the medical men and the Municipal Council, and the general idea in Paris is that the latter has made its economical departure in a maladroit manner and that the failure of the service has been due to irregularity in the way in which the Municipal Council has managed its part of the work. For political reasons and fear of unpopularity the Council is said to have taken no pains to see that they were repaid the fees they had advanced.

A public dinner has been given to Dr. Huchard, a well-known worker in diseases of the heart, by no less than 233 of his fellows, in celebration of his election to the Academy of Medicine.

Dr. Duroziez, also best known for his researches in cardiac pathology, has recently died in Paris. His work hardly met with the official or public recognition that it deserved, for his treatise upon diseases of the heart was widely consulted by the medical profession.

Feb. 1st.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Professor Salvatore Trinchese.

ONE of Italy's most honoured academic figures has departed in Dr. Salvatore Trinchese, sometime Rector of the Neapolitan University and Professor of Comparative Anatomy and Comparative Embryology in that seat of learning. A distinguished *alumnus* of the same school, he succeeded Panceri in 1880 in the anatomical chair, from which he was transferred to the other professorships above mentioned. During his *régime* as Rector (an honour he held twice) he took the initiative, since energetically carried out, for the enlargement and re-adjustment of the University's *curricula*, himself laying the foundation-stone of the new buildings. He was a valued as well as voluminous contributor to scientific periodicals, especially to those bearing on nature-study in its anatomical and embryological relations, and he leaves behind him many works of remarkable merit in general biology. His funeral was largely attended by the academic and scientific world; but as he was in religion what Italians call a "Calvinista" (non-conformist), the function was purely civil.

L'Istituto Kinesiterapico.

Italy has this week brought herself abreast of a movement which, begun in Sweden under the auspices of Major Ling and Dr. Gustav Zander, has been vigorously taken up in Germany and Austria—the movement for the mechanical exercise of the muscles, the joints, and, indeed, of all parts of the system which are apt to get out of gear by sedentary or self-indulgent habits. The Commendatore Beccaro and Dr. Colombo have the credit of this salutary initiative, and in the "Istituto Kinesiterapico" (establishment for the therapeutics of motion), just opened in the Piazza di Termini, they have given Rome a lead which, it is to be hoped, will be followed by other great Italian centres, particularly those which, as seats of learning, offer more inducements to cultivate the mind than the body. In the British Isles athletic sports for the young, and such games as lawn tennis and golf for the middle-aged and elderly, have no counterpart in the continental, particularly the Latin, countries. True, these latter have the fencing saloon and the pistol gallery, but such exercises as these imply, generally in a confined atmosphere and calling into play a very limited proportion of the physical powers, are not for a moment to be compared to the games—football, cricket, golf, or boating—which, pursued *al fresco*, make British youths and men the most finely-developed in the world. Cycling, no doubt, is beginning to be widely practised abroad; but it has its disadvantages—the "kyphosis bicyclistarum," for instance, of continental classification—and needs to be supplemented by other modes of exercise to compensate for the over-pressure of one set of muscles and the comparative inertia of others. Besides, something more systematic than a discipline which can be carried out only "when weather permits" is required, especially in great cities, to counteract the degeneration or worse induced by sedentary life. In spring, in autumn, say the Roman organisers of the "Istituto," the delicious air of the surrounding hills is itself an attraction to out-door exercise; while in summer the resort to mountain or seaboard, or this or that Transalpine, or even Cisalpine "Kur-ort," enables those who can afford it to give the body its due proportion of movement. But in winter this salutary exertion is suspended, the relapse into sedentary life is inevitable, and with it the no less inevitable return of the "degenerations" and "organised incapacities" and "disabilities" which make the professional man or the brain-worker a premature invalid or valetudinarian. In winter, therefore, as, indeed, all the year round, the needs of the sedentary classes are met by the "Istituto," which is conducted on the only sound principle of bodily exercise, that of a gradual evolution of the powers of each organ, the enfeebled or dormant ones first receiving attention till they are brought level with the more normally developed, and the whole system finally endowed with that harmonious balance in which excess in one direction is reduced to atone for restriction in another. To this end accurate measurements are taken of the degree in which a muscle or limb is defective, and the particular exercise or mechanical apparatus which its condition indicates are prescribed and brought into play. No movement is allowed to last more than two minutes, sometimes not even so long. Fatigue, or anything approaching to it, is carefully avoided. Again, when muscular force is so impaired or undeveloped as to be incapable of exertion, electricity is brought in to restore or evolve the missing power till this in turn becomes capable of undergoing the voluntary movements above referred to. Every operation of the professional masseur is indicated by mechanical devices—"tapotement," for instance, being effected by a series of little hammers with elastic covering which keep up a beating movement along the course of a muscle or nerve till a healthy reaction is induced. To enumerate all the appliances in use at the "Istituto" would be to compile a formidable catalogue—a catalogue, moreover, susceptible of almost limitless extension as experience suggests new contrivances. The composition of the assembled public at the opening day supplies a measure of the inspiration under which the "Istituto" has been started and of the social class it is meant to serve. Medicine was represented by its acknowledged heads—academic, clinical, and consultant; while the number of lawyers, merchants, bankers, artists, men of letters, and journalists was a significant indication of the *clientèle* in whose interests

[1] THE LANCET, Jan. 16th, 1897.

Hosted by Google

it has been organised. "Care of the body" is an old tradition of the Eternal City. It is an instructive sign of the limes that that tradition is now so effectively resuscitated, with all the scientific improvement and clinical experience that divides the Rome of the nineteenth century from the Rome of the first.

King Humbert's Body Physician.

Dr. Quirico, sometime physician to the Royal Household, has just been nominated "medico particolare" (special physician) to his Majesty King Humbert.

Jan. 30th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Despatch of a Bubonic Plague Commission to Bombay.

THE Imperial Royal Academy of Sciences has employed a portion of the Treitl Fund in sending a commission, composed of Dr. Hermann Müller, Dr. Ghon, Dr. Albrecht, and Dr. Pöch, to investigate the nature of the bubonic disease now prevailing in India. Dr. Müller is assistant to Professor Nothnagel and is one of the most distinguished of our young medical men. He was born in Gratz in 1860, took the M.D. degree in Vienna at the age of twenty-four years, and was for three years assistant to Professor Ziemssen of Munich. He is at the head of the expedition and is specially charged with the observation of the clinical features of the disease; the post-mortem examinations will be performed by Dr. Albrecht, who is at the present moment assistant to Professor Weichselbaum. The bacteriological examinations are to be made by Dr. Ghon, who is also assistant to Professor Weichselbaum and is well known to the medical world by some publications on bacteriology. Dr. Pöch, attached to the clinic of Professor Neusser, is the junior member of the commission; he is a very able photographer and will assist his colleagues generally. The four medical men will leave Trieste on Feb. 3rd and will remain at Bombay for three or four months. On Jan. 29th they were received by his Excellency Baron Gautsch, Minister of Public Instruction, who complimented them upon their courage and wished them much success in their inquiries. The Treitl Fund is so called after the late Herr Treitl, a Vienna citizen, who bequeathed to the Academy all his fortune, amounting to about £100,000.

The Midwives Question.

The medical profession in Vienna is at last beginning to give some attention to the present condition of its material interests, and the professional journals, which have until now for the most part confined themselves to subjects of purely scientific import, are at present filled with articles on the causes of the decline of medical practice. The medical associations have also taken the matter up, and Dr. Stransky has made a contribution to the discussion which has caused something of the nature of a sensation among the medical profession in Austria. According to him the conditions of medical practice are pitiable; not only have the younger members of the profession at the commencement of their career to encounter great difficulties, but he is aware of a case in which a well-known and very able man, who had been over thirty years in practice, found the pecuniary recompense so inadequate that he abandoned the profession and went into business. If this be so at present it seems probable that practitioners will have to face a still more sombre prospect in the future, for the Government contemplates a further development of the principle of insurance against sickness; such insurance is at present obligatory on the working class, and it will in course of time be extended to employers and tradesmen, so that when this comes to pass medical fees will be at the rate of a penny each visit. Nevertheless, the number of young men entering the profession every year shows no diminution, and the inevitable competition is intensified by the increase of unqualified practitioners, by the gratuitous treatment of well-to-do patients in the hospitals, and by the encroachments of midwives. Not less than a fifth part of the practice in the outlying portions of Vienna is in the hands of the midwives. It is the midwife who is first sent for when illness makes its appearance, and it is she who decides whether it is necessary to call in a medical man. Midwives undertake the treatment of cases of abortion and premature birth, they make examinations, remove retained portions of the ovum or placenta, and perform irrigations with antiseptic solutions prepared by themselves. When adherent placenta or atony of the uterus causes hæmorrhage they give ergotine, and obtain medical aid only when there is fever. It is not surprising, therefore, that in shoulder presentations turning is not performed in proper time, and that extensive lacerations of the perineum occur. Midwives also treat children's diseases, especially scarlet fever, measles, and small-pox, by herbal infusions and poultices, and they dissuade the parents from sending for a medical man, saying that if the doctor comes he will notify the case to the authorities and the house or apartment will have to be disinfected. They treat disease of the eyes of new-born children with applications of milk or urine; if eclampsia occurs the sick woman's wedding veil is put on, and if no improvement follows from the use of this traditional remedy a medical man is called in with a view to avoiding unpleasantness and preventing a post-mortem examination. How is this state of affairs to be remedied? asks Dr. Stransky. The obvious answer would be: By the enforcement of the laws against unqualified practice. But law is uncertain, and if a midwife were punished her practice would increase, for the public would look on her as a martyr persecuted by the medical men. Moreover, the midwives are so efficiently organised that a medical man making a complaint against one of them would seriously endanger his position, and Dr. Stransky mentioned an instance of a man who lost his obstetric practice in consequence of taking action against a midwife in connexion with a case of abortion. Dr. Stransky suggested that the Health Office should take energetic steps in the matter, and he strongly condemned the conduct of some medical men who send out circulars to midwives soliciting recommendations to patients.

Jan. 31st.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

The Government Lunatic Asylum.

THE total number of lunatics under treatment during the year 1896 was 910, of whom 182 were discharged recovered, 154 relieved, 66 unrelieved, 13 not insane, and 81 died. The average daily number of resident inmates was 477, having varied from 411 to 514. The admissions were 422 and included the following: mania, 147; puerperal insanity, 2; mania from hasheesh, 49; intoxication from hasheesh, 17; dementia from hasheesh, 19; mania of persecution from hasheesh, 3; dementia, 54; idiots, 3; epileptics, 17; general paralysis, 29; chronic mania, 11; pellagrous melancholia, 8; &c. The 81 deaths during the year were due to—tubercle, 23; general paralysis, 13; pellagra, 3; ankylostomiasis, 2; cholera, 10; diseases of the nervous system, 11; all other diseases, 19. The causes of insanity could not be discovered in 127 patients, though many of them were consumers of hasheesh; but the following causes, among others, were registered: hasheesh, 88; alcohol, 9; syphilis, 27; pellagra, 11; epilepsy, 17; sunstroke, 2; grief, 30; and religious excess, 16.

Hasheesh Lunatics.

At least a quarter, and probably one-half, of the male cases are due to an abuse of hasheesh, as has often been pointed out before. The average residence in the asylum of discharged cases was forty days. A few of the patients confessed to opium-eating besides the hasheesh habit, and the seven women admitted during the year were all prostitutes or servants in hasheesh dens.

General Paralysis.

From Dr. Warnock's investigation during the last two years it seems evident thas this disease is commoner in Egypt than has been supposed. It will be noted from the figures quoted above that nearly 7 per cent. of the year's admissions, besides 16 per cent. of the deaths, were due to general paralysis. The following table is worth quoting as showing that the Egyptians themselves, as in 1895, furnished the bulk of the cases:—

Nationality.	Male.	Female.	Total.
Egyptian	17	6	23
Greek	3	1	4
Jewish	1	—	1
Syrian...	1	—	1

Hosted by Google

The Egyptians came from the poorest and least educated classes, such as pedlars, servants, and artisans, and there was one peasant among them. Syphilis was found to have existed in nearly every one of them, and when it is remembered that in this country syphilis is practically untreated we probably have the most marked causal element of general paralysis among the Egyptian poor. Several patients upon admission bore upon their heads broad scars due to the application of the actual cautery in their villages, for the native firmly believes that fire will burn away any disease or frighten away the demon possessing the patient. He also believes that a dangerous lunatic should make the round of certain extra-religious mosques in the hope of a cure. These enforced pilgrimages sometimes result in the commission of crimes on innocent people.

Improvements in the Asylum.

A recent letter described some of this year's reforms under Dr. Warnock's superintendence, and though £4000 has been voted for past necessities, it is obvious that at least a similar sum must be forthcoming from the finance authorities if all the crying evils are to be remedied. In the meantime overcrowding has been greatly lessened, and the superficial area in the bedrooms has been raised from an average of fifty-two square feet per patient to seventy-six square feet. The actual figures now vary from a minimum of sixty-three to a maximum of ninty-five square feet. Water is now laid on to all floors, together with sinks and Pasteur-Chamberland and Berkefeld filters. Each section has been provided with a dining-room and a great deal has been done to humanise the unfortunate patients. It is only twelve years ago that the native director of the sanitary department refused to sanction extra expenditure at this asylum on the grounds that the insane were wild animals, and should be treated as such!

Decorations for Cholera Work.

Of late years the Khedive has decreed that honours shall be bestowed upon Government employés chiefly upon two occasions in the year. The gazette to celebrate His Highness's accession to the throne has just been published. No less than 226 officials were honoured by appearing in it, and it was prophesied on all sides that a well-deserved compliment would be paid to the English and native doctors who had worked for twelve months, not without success, against cholera. But the Khedive and his English advisers thought differently and determined to issue as few rewards as possible and to let those few take the form of inferior decorations. It is not dignified to do more than protest against this ungenerous policy, which stands out in marked contrast to the lavish decorations and promotions showered upon the Egyptian army after six months spent in re-capturing Dongola. Four European sanitary officers were selected from a list of twelve recommended. They were Dr. Rogers Pasha, who received the Second Class Osmanieh, a decoration which would have appeared more valuable if it had not been given at the same time to his native subordinate. Dr. Schiess, the Swiss Director of the Government hospital at Alexandria, was given the Third Class Order of the Medjidieh after thirty years' painstaking work for Egypt; and a similar decoration was awarded to Mr. Pinching, on whom the burden lay of inspecting half of the country during the long cholera campaign. The names of Dr. Graham and of Dr. Garner are entirely omitted from the list, though it is well known that they distinguished themselves in no common way for a whole year. The remaining decoration, the Fourth Class of the Osmanieh, was given to Dr. Bitter (a German) for much hard work in Alexandria. Curiously enough, none of the European workers in Cairo have received anything. Sixty natives were recommended for reward, but only twenty were approved of.

Absence of Cholera.

Some interest was created in Egypt last week by a Reuter's telegram stating that some persons on board the Peninsular and Oriental Company's steamship *Nubia* had contracted cholera at Port Said on her way from India to London in December. As a matter of fact Port Said enjoyed a singular immunity from cholera during the late epidemic, and there has not been a single case of cholera in all Egypt since the middle of October.

Commission to Study Plague.

The accounts of plague from the Bombay presidency are so unsatisfactory that Dr. Rogers Pasha has obtained leave from the Egyptian Government to proceed there to study the disease on the spot and the regulations necessary to ensure the prevention of its entry into Egypt. He is accompanied by Dr. Bitter, now head of the new Institute of Hygiene, and by Dr. Ibrahim Pasha Hassan, chief of the Medical School.

Cairo, Jan. 20th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Prevention of the Spread of Tuberculosis.

IT appears that nearly 9000 cases of phthisis were reported to the New York Board of Health in 1896, and nearly 6000 deaths resulted from the disease. It is conservatively estimated that at least 20,000 cases of well-developed and recognised phthisis now exist in this city, and an additional large number of obscure and incipient forms of the disease. A very large proportion of these 20,000 cases constitute more or less dangerous centres for infection, the degree of danger depending upon the intelligence and care exercised. It may be safely assumed that from the failure to exercise proper care from 30 to 50 inhabitants of this city daily become infected by phthisis, and of these about one-half die later from the disease. The directors of the Department of Bacteriology of the Board of Health state that they fully believe that with proper regulations tuberculosis may be restricted within the narrowest bounds and eventually, perhaps, almost exterminated. This is not the idle dream of sanitary enthusiasts or theorists, but is a conviction founded upon the most thorough and conclusive experimental investigations, which have been amply confirmed by practical experience. They recommend that a hospital for phthisical patients be established under the charge of the Board, where the poor, who are active sources of danger to the community, may be cared for; that the Sanitary Code is to be so amended that phthisis will be officially considered a communicable disease and regulations for its surveillance be formulated; that all institutions which treat phthisical patients are to be regularly and systematically inspected by officials of the Board and that better measures be taken to educate the people as to phthisis and the methods of preventing it; and that a closer sanitary inspection be exercised over phthisical patients in densely populated districts, in crowded workshops, and in public buildings.

Statue of Dr. Samuel D. Gros.

The statue of the late Dr. Samuel D. Gross by A. Sterling Calder, recently cast in Paris, will soon be erected on the grounds of the Smithsonian Institute at Washington. The movement for the erection of a statue to Dr. Gross was begun by the American Medical and Surgical Association, of which he was founder and first president. With the coöperation of the *alumni* of Jefferson Medical College and other warm personal and professional friends the necessary funds were collected. Congress appropriated a sum sufficient for the erection of a suitable pedestal, and the monument is to be unveiled by a granddaughter of Dr. Gross during the next Congress of Physicians and Surgeons in Washington. This statue is the second of its kind erected in this country to a physician, the other, in New York, being to Dr. J. Marion Sims, a personal friend and contemporary of Dr. Gross.

An Enormous Lying-in Hospital.

A citizen of New York has given $1,000,000 to the Society of the Lying-in Hospital of the City of New York for the erection of a hospital. There are over 26,000 children born in this city every year whose mothers are without medical aid. The hospital will care for 6000 patients yearly. It will have a width of 83 ft. in Seventeenth-street and of 116 ft. in Eighteenth-street, with a frontage of 184 ft. in Second-avenue. It will be ten storeys high and will have a fire-proof construction of steel, brick, and stone. The lower part will be built of granite and the superstructure will be of yellow brick with granite facings. The main entrance to the hospital will be on the Avenue, and side entrances will open in Seventeenth-street and Eighteenth-street. A dormitory and sitting-room for students will have a place on the basement floor, which will also contain a large clinic hall and instruction room, a kitchen, a sewing-room, and an attendants' dining-room in the rear. On the cellar floor, besides the furnaces, dynamo-rooms, and store-rooms, there will be a laundry, several rooms for servants and attendants, and a disinfecting apartment. The executive

Hosted by Google

department of the hospital, with the necessary offices, will be on the first or main floor. Here, too, will be a museum, a lecture-room, the dining-room for students, and rooms for nurses and attendants. The second, third, fourth, fifth, and sixth storeys will be constructed on a uniform plan. They are to be used for the wards and will eventually contain 250 beds for patients. On the seventh storey the operating-room will be placed, together with a room designed for the storing of instruments and apparatus. This floor will also contain the private room for nurses. Nurses' rooms and rooms for graduate students, of whom there were more than 300 at the hospital between Oct. 1st, 1895, and Sept. 30th, 1896, will be found on the eighth floor. There will be an aseptic laundry here and a diet kitchen, besides a large amphitheatre, which will extend up through the ninth floor. The pathological laboratory and a laboratory for the special study of microbes will have a place on the tenth floor.

Organisation of the Trained Nurses of America.

The Trained Nurses' United Aid Society of America is the name of a large organisation recently incorporated in this country. The movement is in the interest of at least 6000 trained nurses now being employed in the United States. Its object is the relief of members whose professional activity is suspended on account of illness or accident, and in case of death the payment of funeral expenses. Homes of rest, loans of money in case of temporary distress, an invalid fund, endowed beds, and pensions are other advantages which will be added.

Emergency Rations for the Army.

A board of army officers has concluded its investigations as to the quality and quantity of an emergency ration for soldiers. As a result the Secretary of War has issued the following: "The President hereby establishes an emergency ration for troops operating for short periods under circumstances which require them to depend upon supplies carried upon their persons. Its component parts are as follows: bacon, 10 oz.; hard bread, 16 oz.; pea-meal, 4 oz., or an equivalent in approved material for making soup; coffee, roasted or ground, 2 oz., or tea, 1½ oz.; saccharin, 4 grains; salt, 0·64 oz.; pepper, 0·04 oz.; tobacco, ½ oz." The Secretary of War also adds that this emergency ration must be resorted to only on occasions arising in active operations when the use of the regularly established rations may be impracticable.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Adelaide Hospital Inquiry.

OWING to the termination of the Parliamentary session the Select Committee of the Legislative Council appointed to inquire into the disputes at the Adelaide Hospital has ceased before it had nearly completed its investigations. In its report it recommended that the inquiry be continued by a Royal Commission. The Government declined to appoint a Royal Commission, as in its opinion "no good result would follow." Dr. Leith Napier and Dr. Ramsay Smith have, however, at the request of the Government compiled a report in answer to the evidence taken by the Committee from Dr. Corbin and Dr. Moule. The main charges contained in this evidence were summarised in a previous communication.[1] Subsequently under cross-examination Dr. Corbin made a statement which created some sensation and has been made capital of by Dr. Napier in his reply. When asked why he did not interfere sooner and prevent Dr. Napier making the alleged surgical blunders Dr. Corbin said (as reported in the press—the evidence has not yet been published by authority): "I thought the greatest good to the greatest number was far more to be considered, and I did not interfere because I hoped he would kill the man on the table and so damn himself for ever. I thought if one case could raise the indignation of this sluggish public that perhaps many lives would be saved." He subsequently explained that he did not mean what he said: "It never occurred to me at the time to allow the patient to die on the table; the very fact of my interference shows that. It occurred to me since that possibly the greatest good to the greatest number would have been achieved by Dr. Napier actually killing a patient on the table, and that was in my mind, perhaps, when I made the answer at the end of a tiring and harassing cross-examination." Dr. Napier's report in reply is in the main a denial of the facts, which he says, have been falsely and maliciously misrepresented by Dr. Corbin, Dr. Moule, and Professor Watson, who, he alleges, had entered into a conspiracy against him. In the case of supra-pubic lithotomy in which the peritoneum was opened and not closed, he says the opening was unavoidable; that having been opened it was better to leave it open and drain; and that the patient did not die from peritonitis, as Professor Watson's report of the necropsy stated, but from the effects of ether badly administered. In the case in which he explored the kidneys by abdominal section he maintains that the method he adopted was correct and expresses astonishment that an anatomist like Professor Watson should be so ignorant as to assert that the left renal vein is longer than the right. In the case of laparotomy for hydatid he also maintains that his method of operation was correct and observes that the Adelaide surgeons have originated nothing in regard to the modern treatment of hydatids, which he claims to have been evolved by Mr. Lawson Tait. The case of carcinoma of the mouth which, according to Dr. Corbin, was diagnosed as "rhinolith," Dr. Napier says he called a "ranulith," a name coined by himself for some forms of ranula. Concussion of the spinal cord by *contre-coup* is, he says, a condition well known to neurologists. Dr. Smith's report is chiefly a condemnation of the hospital arrangements at the time he took office, and he asserts that "neither house surgeons nor nurses could be trusted where the lives of patients were at stake."

Annual Meeting of the Victorian Branch of the British Medical Association.

At the annual meeting of the Victorian branch of the British Medical Association the following were elected office-bearers for the ensuing year:—President: Mr. Stirling. Vice-President: Dr. McAdam. Hon. Treasurer: Dr. J. R. M. Thomson. Hon. Sec.: Mr. W. Kent-Hughes. Hon. Librarian: Dr. Felix Meyer. Council: Dr. A. V. Anderson, Dr. Gresswell, Mr. Kenney, Dr. O'Sullivan, and Dr. Springthorpe. Dr. O'Sullivan, the retiring President, delivered an address, in which, after referring in eloquent terms to the services to science of the late Baron von Mueller (one of the original members of the branch), he noticed the developments in connexion with the Roentgen rays, and expressed his belief that their long-continued action might be found to exert a salutary effect in several pathological states. He regarded the results obtained by Coley, Emmerich, and Scholl as conclusive as to the curative effect of erysipelas serum on malignant tumours. The apathy of the public in establishing infectious fever hospitals was denounced in forcible language. In the domain of gynæcology, his own speciality, the retiring President alluded to the advances in the technique of hysterectomy, avowing himself a warm advocate of panhysterectomy. He traced a number of the ills of women to the use of measures adopted to prevent conception, and urged the profession to denounce these procedures with no uncertain voice. He was convinced too that cycling was injurious to women. He asserted that nerve strain was at its highest in cycling—the brain, the eyes, the ears, the hands, and the feet must be ever on the alert and act in harmony, and remembering the close relationship between the brain and the generative organs the almost inevitable result must be harmful.

The Macleay Lectureship in Bacteriology.

The late Sir William Macleay left a sum of £12,000 to establish a lectureship in bacteriology in Sydney in the first instance in connexion with the University, but, as explained in a previous communication, the Senate decided that the University could not fulfil the conditions.[2] In accordance with the terms of the will the bequest was then handed to the Linnean Society of New South Wales. The council of that society, however, was not in a position to equip a laboratory at the time, but decided to allow the capital to accumulate. The council now has a sufficient sum for a proper equipment, and is advertising for a lecturer, who will be required to devote his whole time to his duties at a salary of £350 a year and two-thirds of the fees received from students. He will be required to devote his time

Hosted by Google

primarily to original research, under the orders and control of the council, and at the discretion of the council may also give instruction to a limited number of pupils, the number and fee to be fixed by the council.

The Chair of Physiology at the Melbourne University.

Dr. G. B. Halford, who has occupied the chair of Physiology ever since the Melbourne Medical School was founded, has for some time, from the effects of age and failing health, been unable to fulfil the duties of his office in a thoroughly satisfactory manner. Some time ago he resigned, but on finding that the council did not propose to give him any retiring allowance he promptly withdrew his resignation. He has now been granted twelve months' leave of absence on half-pay and Dr. C. J. Martin, Demonstrator of Physiology in Sydney University, has been appointed to do the work of the chair at a salary of £500 a year and the status of lecturer, and it is generally understood that when Professor Halford finally retires Dr. Martin will be appointed professor. The chair originally included anatomy and pathology as well as physiology, but in 1881 was divided, and Dr. H. B. Allen made first lecturer on, and then professor, of anatomy and pathology. Some time ago there was talk of dividing this chair into two, leaving Professor Allen to pathology, which is quite sufficient for one man, but owing to want of funds nothing has been done.

BUBONIC PLAGUE IN BOMBAY.

THERE were 97 deaths from plague reported from Bombay on Tuesday, the 2nd inst., out of a total mortality of 282. At Karachi 51 cases out of 59 died, making a total of 853 deaths in that town out of 930 cases. The disease also exists in Poona, Gao, and Daman, and in Baluchistan. In Poona up to date there had been 58 indigenous cases—48 in one quarter and no cases in the cantonment. So far as is known Calcutta is not as yet affected.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the First Examination of the Board under the five years' regulations in the subjects indicated at the quarterly meeting of the Examiners:—

Part I., Chemistry and Physics:

Baggs, James Charles, St. Thomas's Hospital.
Bailey, Lionel Danyers, St. Paul's School, West Kensington.
Barrett, Henry Edward, St. Mary's Hospital.
Beet, William Ashley, London Hospital.
Bennett, Charles Harold, St. Mary's Hospital.
Bennett, Kenneth Hugh, University College, London.
Bennette, Horace Willie Paul, University College, Liverpool.
Bettinson, George, St. Mary's Hospital.
Brice, Henry Doyle, Westminster Hospital and the Pharmaceutical Society's School.
Camacho, Angelo, St. Paul's School, West Kensington.
Chell, George Russell Haines, Mason College, Birmingham.
Clayton, John Cecil, University College and Clifton Laboratory, Bristol.
Crass, Gerald, Coneybeare, Middlesex Hospital.
Cumberbatch, Elkin Percy, St. Paul's School, West Kensington.
Dalzell, Arthur Montgomerie, St. Bartholomew's Hospital.
De Carteret, Sylvester, St. Bartholomew's Hospital.
Dodd, Archibald Stewart, St. Mary's Hospital.
Douse, John Freeman, Guy's Hospital.
Edwards, Arthur Baynes, St. Bartholomew's Hospital.
Fawssett, Wilfred, King's College, London, and St. Thomas's Hospital.
Fisher, Charles, St. Bartholomew's Hospital.
Fort, Percy Reginald, St. Mary's Hospital.
Foster, Edward Cecil, University College, London.
Goodair, Percy Hamilton, St. Thomas's Hospital.
Gray, William Harrington, London Hospital.
Green, Arthur Llewellyn Baldwin, St. Bartholomew's Hospital.
Hackney, Gordon Herbert, University College, London.
Hanbury, Langton Fuller, St. Thomas's Hospital.
Hanbury, Reginald Janson, St. Bartholomew's Hospital.
Harris, William Trengweath, St. Thomas's Hospital.
Harrison, Edward Montague, St. Paul's School, West Kensington.
Haydon, Maurice Willoughby, St. Thomas's Hospital.
Howkins, Cyril Henry, Mason College, Birmingham.
Huddart, Cuthbert Edmund Arnold, London Hospital.
Jeremy, Harold Rowe, London Hospital.
Jones, John Pugh, University College of South Wales, Cardiff.
Jones, Sydney Herbert, King's College, London.
Kidd, Basil Symonds, St. Mary's Hospital.
Lindsey, Eric Craigie, St. Mary's Hospital.
Mathews, William L'Estrange, Mason College, Birmingham.
Miller, Frederic William, King's College, London.
Mitchell, Talbot Carter, Yorkshire College, Leeds.
Pank, Harold William, St. Bartholomew's Hospital.
Prins, Henry Mallock, University College, London.
Raven, Hugh Milville, St. Mary's Hospital.
Richard, George Herbert, St. Paul's School, West Kensington.
Sale, John Caruthers, St. Bartholomew's Hospital.
Small, Robert, St. Thomas's Hospital.
Soper, George Bertram, Guy's Hospital.
Stephenson, Robert West, University College, Liverpool.
Tatchell, William Arthur, London Hospital.
Thompson, Reginald, St. Bartholomew's Hospital.
Tovey, Arthur Hamilton, St. George's Hospital.
Turtle, Godfrey de Bee, King's College, London.
Vincent, George Bernard, St. Paul's School, West Kensington.
West, John Arthur, St. Bartholomew's Hospital.
Whitwell, Hugh, St. Bartholomew's Hospital.

Part II., Practical Pharmacy:

Adams, Henry Cyril, St. Bartholomew's Hospital.
Baker, William Langworthy, Guy's Hospital.
Bell, Kenneth de Risley, King's College, London.
Bigg, Reginald, St. Bartholomew's Hospital.
Blizzard, Walter Harry Stanley, Mason College, Birmingham.
Brice, Henry Doyle, Westminster Hospital.
Brown, Evelyn Kempson, London Hospital.
Bullmore, Edward Augustus, University College, London.
Clitherow, Herbert George, London Hospital.
Couzens, Alfred John, London Hospital.
Forster, Frederick Cecil, St. Mary's Hospital.
Fuller, Laurence Otway, University College, London.
Gaitskell, Charles Edward, Guy's Hospital.
Gleig, Percy North, Charing-cross Hospital.
Heath, Francis Harold Rodier, Guy's Hospital.
Hewer, Edward Septimus Earnshaw, St. Bartholomew's Hospital.
Hollick, Hubert Harry, Mason College, Birmingham.
Irvine, Guy Harle, University College, Bristol.
Jones, John Pugh, University College of South Wales, Cardiff.
Joy, Norman Humbert, St. Bartholomew's Hospital.
Kilpatrick, James Armstrong, University College of South Wales, Cardiff.
Kirkman, Albert Henry Beaumont, Guy's Hospital.
McGavin, Laurie Hugh, Guy's Hospital.
Maher, Michael Robert, University College, Liverpool.
Maugham, William Somerset, St. Thomas's Hospital.
Mondy, Samuel Lee Craigie, University College, London.
Morris, Isaac Llywellyn, St. Bartholomew's Hospital.
O'Meara, Eugene John, Guy's Hospital.
Palgrave, Edward Francis, St. Bartholomew's Hospital.
Parsons, Arthur Ruscombe Crane, King's College, London.
Phillips, Nathaniel Richard, University College of South Wales, Cardiff.
Pugh, Arthur Bailey, St. Bartholomew's Hospital.
Ramsay, Palmer Devoy, St. Mary's Hospital.
Rees, Henry Melville, Owens College, Manchester.
Richards, Ramsey Martyn, St. Mary's Hospital.
Ryley, Charles, St. Mary's Hospital.
Shattock, Charles Robert, King's College, London.
Sheldon, Walter Sirr, University College, London.
Stanley, Arthur John, Mason College, Birmingham.
Tarbet, Peter Rowley, University College, London.
Thomas, Arthur Richard, Guy's Hospital.
Timothy, John Haydon, University College of South Wales, Cardiff.
Wadmore, James Christopher, University College, Bristol.
Walter, John Basil, Guy's Hospital.
Watson, John Harry, University College, Liverpool.

Part III., Elementary Biology:

Ackery, Edward Faulkner, Charing-cross Hospital.
Allan, Charles Henry, London Hospital.
Bannerman, Charles Harold, University College, Liverpool.
Bennette, Horace Willie Paul, University College, Liverpool.
Boclett, Jaustin Marcel, Charing-cross Hospital.
Brice, Henry Doyle, Westminster Hospital.
Carling, Ernest Rock, Westminster Hospital.
Clitherow, Herbert George, London Hospital.
Couper, James, Charing-cross Hospital.
Davies, Charles Woolmer, St. Thomas's Hospital.
Davies-Ooranofski Vladimir, Anderson's College, Glasgow, and University College, Liverpool.
Dix, Charles, St. Bartholomew's Hospital.
Douse, John Freeman, Guy's Hospital.
Downes, Thomas William Hardwick, St. Thomas's Hospital.
Drabble, Charles Clement, Firth College, Sheffield.
Drinkwater, Frederick Andrew, University College, Liverpool.
Fawssett, Wilfrid, St. Thomas's Hospital and King's College, London.
Fowler, Trevor Hayman, St. Bartholomew's Hospital.
Graves, Robert Kennedy Grogan, St. George's Hospital.
Grote, Robert George Ernest, Charing-cross Hospital.
Hamill, John Molyneux, St. Paul's School, West Kensington.
Hemans, Thomas Daniel, St. Thomas's Hospital.
Hendley, Phillip Arthur, King's College, London.
Hughes, Thomas Hugh James Ellis, St. Mary's Hospital and King's College, London.
Jackson, Frederick Douglas Selmes, Guy's Hospital.
Jeremy, Harold Rowe, London Hospital.
Jobson, Frederick Cuthbert, Westminster Hospital.
Lindsey, Eric Craigie, St. Mary's Hospital and King's College, London.
Margetts, Horace Palmer, St. Bartholomew's Hospital.
Marsh, James Kenneth Nevil, St. Bartholomew's Hospital.

Hosted by Google

Martyn, Frank Derecourt, Westminster Hospital.
Michel, Arthur George, Charing-cross Hospital.
Morgan, Frank, Westminster Hospital.
Morrow, David, Queen's College, Belfast.
Nesfield, Vincent Blumhardt, St. Paul's School, West Kensington.
Richards, Thomas, University College of South Wales, Cardiff.
Roberts, John Hamilton, Charing-cross Hospital.
Sale, John Curuthers, St. Bartholomew's Hospital.
Sampson, Bernard Moore, St. Thomas's Hospital.
Scott, Edward Spencer, London Hospital.
Soden, Arnold Edward, McGill College, Montreal, Canada.
Stephenson, Robert West, University College, Liverpool.
Van Dyk, Adriaan François, School of Medicine, Surgeon's Hall, Edinburgh.
Williams, Sidney James, Mason College, Birmingham.

The following gentlemen passed the First Examination of the Board under the four years' regulations:—

Part I., Chemistry, including Chemical Physics:

Dudley, Samuel Robert, St. Bartholomew's Hospital.
Houchin, Edwin Augustus, Middlesex Hospital.
Magee, Charles Crozier Tandy, Melbourne University and London Hospital.

Part II., Materia Medica:

Bell, Victor Samuel Alexander, Cambridge University and St. Bartholomew's Hospital.
Clough, Harry, Yorkshire College, Leeds.
Cooper, Frank, Mason College, Birmingham.
Elvins, Ralph Sedgeley, Mason College, Birmingham.
Gould, Horace John, Middlesex Hospital.
Grantham-Hill, Wilfred St. George, St. Mary's Hospital.
Magee, Charles Croezier Tandy, Melbourne University and London Hospital.
Phillips, Philip, Charing-cross Hospital.
Pierce, George Oliver, King's College, London.
St. John, Winstan St. Andrew, St. Mary's Hospital.
Sandison, James, London Hospital.
Sowden, George, London Hospital.
Towers, Henry, Yorkshire College, Leeds.
Voller, Frank, St. Thomas's Hospital.
Waldmeier, Frederick John, Syrian Protestant College, Beyreut, Syria, and London Hospital.
Whyte, Frederick William, Queen's College, Belfast.

Part III., Elementary Physiology:

Elliott, William Robert, Cambridge University.

UNIVERSITY OF CAMBRIDGE.—On Jan. 28th the following graduates of the University were admitted to degrees in Medicine and Surgery:—

M.B. and B.C.—F. A. C. Tyrrell, B.A., Clare; and J. Hobday, B.A., Christ's.
M.B. only.—R. A. Kirby, B.A., Trinity; and G. C. Taylor, M.A., Christ's.
B.C. only.—L. P. Black, B.A., Trinity Hall.

Mr. Walter Gardiner, F.R.S., has resigned his University lectureship in Botany on his appointment to the Bursarship of Clare College. Eighteen additional freshmen were matriculated on Jan. 28th, making the entry for the year 923.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. René du Bois-Reymond and Dr. Ruge have qualified as *privat-docenten* of Physiology and Internal Medicine respectively.—*Bologna:* Dr. Angelo Pugliese has qualified as *privat-docent* of Physiology.—*Florence:* Dr. Ernesto Pestalozza has been appointed Professor of Midwifery and Gynæcology.—*Geneva:* Dr. Johannes Martin has been appointed Professor of Psychiatry in succession to Dr. Olivet, who is retiring.—*Groningen:* Dr. Wiersma has qualified as *privat-docent* of Psychiatry.—*Iurieff (Dorpat):* Dr. Kessler has been appointed Extraordinary Professor of Gynæcology. Professor E. R. Kobert is resigning the chair of Pharmacology and is about to take the post of Director of the Brehmer Sanatorium in Vienna.—*Leipzig:* Dr. A. Heffter has been appointed Extraordinary Professor of Pharmacology.—*Modena:* Dr. Arnaldo Maggiora has been appointed Professor of Experimental Hygiene.—*Munich:* Dr. Johann Rückert has been appointed Professor of Anatomy.—*Padua:* Dr. Alessandro Serafini has been appointed Professor of Experimental Hygiene. Dr. Gregorio Manca has qualified as *privat-docent* of Physiology.—*Palermo:* Dr. Vincenzo Acquisto has qualified as *privat-docent* of Histology.—*Rome:* Dr. V. Ascoli has qualified as *privat-docent* of General Pathology.—*Strassburg:* Dr. P. Manasse has qualified as *privat-docent* of Otology.

THE following telegram to the Secretary of State for the Colonies has been received from the Governor of Gibraltar: "Jan. 27th, 1897.—Vessels from India will not get pratique at Gibraltar and will not be allowed to land passengers or goods. Mails and specie will be landed in quarantine and coals and provisions supplied in quarantine."

PROFESSOR SHERRINGTON, F.R.S., of University College, Liverpool, will deliver an address at the College of Medicine, Newcastle, on Thursday, Feb. 18th, upon Researches on the Spinal Segment.

PRESENTATIONS TO MEDICAL MEN.—Dr. E. W. Joscelyne, of Southwick, has been the recipient of a silver fish knife and fork and a silver mounted pipe by the members of the Southwick ambulance class, and as a present on his approaching marriage, in recognition of his instructive lectures on First Aid.—Mr. Sinclair Finlay, L.K.Q.C.P., F.R.C.S.Irel., of Stroud, New South Wales, was presented, at a public entertainment on Nov. 14th last, on the occasion of his departure from that locality, with a valuable gift of plate from the residents of Port Stephens district.—Mr. George A. Phillips, M.R.C.S.Eng., of Walsall, has been the recipient of a beautiful illuminated address in a neat frame from the members of the London and North-Western Railway Permanent Way Department ambulance class at the Walsall station, as a thank-offering for his services as instructor in First Aid.—Dr. Richard C. Shettle of Reading was presented, at a meeting of the medical and surgical staff of the Royal Berkshire Hospital, on the 21st ult., at which all the members were present, with a pair of silver candlesticks. The occasion was to wish him good-bye on his resigning the office of physician, which he had held for a period of twenty years.—Mr. Robert Kennedy, M.A., M.D. Glasg., has been presented with a handsome barometer in recognition of his services as lecturer to the Queen-street station ambulance class.—Mr. R. Wilson Bruce, L.F.P.S. Glasg., has been presented with a testimonial by the members of the Glasgow police force on the occasion of his resignation of the position of casualty surgeon to the northern police district.

CHANGES AT THE LIVERPOOL ROYAL INFIRMARY.—The annual meeting of the trustees of the Liverpool Royal Infirmary, held on Saturday last, presented features of more than ordinary interest. Its proceedings included the announcements of the retirement of Mr. Hamilton B. Gilmour from the chairmanship, after an occupancy of nineteen years; and of the resignation of Dr. Alexander Davidson of the honorary physiciancy which he held for twenty years. Universal regret is felt at the Royal Infirmary that Dr. Davidson should have thought fit to resign active duties there. Happily, his resignation has not been due to age or infirmity, as he is in robust health. Mr. H. B. Gilmour's retirement from the chairmanship of the General Committee is also much regretted by his colleagues and others; he was chiefly instrumental, in conjunction with a portion of the medical staff, in the reconstruction of the magnificent building which is looked upon as one of the best constructed and equipped hospitals in Europe. A more zealous and efficient chairman it would be difficult to find. His courtesy, forethought, and attention to minute details, and his constant consideration for the comfort of the officials, nurses, &c., are warmly acknowledged by all connected with the institution. Mr. Mitchell Banks, on behalf of the medical staff, alluded in feeling terms to the kindly relations which had always existed between the chairman and the staff, and described Mr. Gilmour's conduct in the chair as distinguished by urbanity, justice, and forbearance—qualities which had enabled him to smooth over many difficulties. His "quiet tact and happy behaviour had prevented molehills from growing into mountains of dissatisfaction." Some three or four years ago Mr. Gilmour's colleagues on the committee presented him with his portrait painted in oils, which now adorns the board room. The present "committee of management" was first formed concurrently with the completion of the second hospital building in 1823, previously to which the management was vested in a "weekly board." The first chairman of the newly-constituted committee was the late Mr. Edward Gibbon, who held the office (with the exception of one year) until the year 1850. His son, the present Mr. Edward Gibbon, succeeded him in the chair, which he resigned in 1878. Mr. H. B. Gilmour was then unanimously elected to preside over the committee. The trustees have now further honoured him by conferring on him the presidency, a post which is usually held for one year and which numbers amongst its late occupants the Marquis of Salisbury, K.G., Earl Derby, Earl Harrowby, and Earl Lathom. Dr. Davidson was elected an honorary consulting physician at the same meeting.

Hosted by Google

A BALL in aid of King's College Hospital will be held at the Queen's Hall, Langham-place, on Wednesday, Feb. 24th. Information may be obtained of Mrs. Wace, King's College, London.

THE reading of Dickens's Christmas Carol, given by Mr. Bancroft at the London Hospital on the evening of Feb. 1st, resulted in a cash profit of £150 to the charity.

BUDLEIGH SALTERTON COTTAGE HOSPITAL.—The eighth annual meeting of the Budleigh Salterton Cottage Hospital was held on Jan. 14th, Dr. T. N. Brushfield presiding. The honorary secretary stated that the committee considered the finances to be in a satisfactory condition as there is a balance in hand of £98 as against £96 last year. The committee reminded the inhabitants of Salterton and district that this hospital is a "Jubilee" memorial, and think that as a commemoration of the Queen's sixty years' reign it would be appropriate to make it a model cottage hospital by the erection of a porter's cottage with laundry attached and a suitable mortuary chamber. The following gentlemen were elected on the staff: Honorary Consulting Physicians, Mr. T. N. Brushfield, M.D. St. And., M.R.C.S.Eng.; Mr. R. Walker, M.D.St. And., M.R.C.S.Eng. Medical officers — Mr. T. G. C. Evans, M.R.C.S. Eng., L.R.C.P. Edin.; Mr. H. F. Semple, M.R.C.S. Eng., L.R.C.P. Lond.

THE SUSSEX COUNTY HOSPITAL.—Exactly eleven months on Friday, Jan. 29th, the Prince of Wales laid at Brighton the foundation-stone of the new out-patients' department of the Sussex County Hospital, and on Friday Her Royal Highness the Duchess of Fife, accompanied by her husband, opened the department. The building stands on the opposite side of the road facing the hospital, and is only one storey high, though of good elevation. The main entrance leads to the waiting-room, which is 92 ft. by 26 ft.; at the rear are a double set of examination rooms for the surgical and medical staff, with dressing and bathrooms attached, and a dark room for ophthalmic cases and the dispensary. The heating is by hot water and electric light is used. The mayor (Alderman Blaker), the chairman of the committee of management (Mr. G. D. Turnbull), the staff, and officials of the institution and other ladies and gentlemen assisted in the ceremony, which was witnessed by a large number of visitors. The whole of the money laid out on the building has been subscribed.

PRESENTATION TO MR. F. D. MOCATTA.—An interesting ceremony took place on Jan. 27th at the Jews' Free School, Spitalfields, on the occasion of the presentation of an album of addresses and signatures to Mr. Mocatta, who has just entered upon his seventieth year. Lord Rothschild occupied the chair, and among those present were Sir Philip Magnus, Professor Meldola, Sir William Vincent, Mr. Isidore Spielman, Mr. Cecil Sebag-Montefiore, Dr. Gaster, Professor Marks, and Sir Samuel Montagu, M.P. The address contained in the album was a fitting expression of the appreciation of the benevolence of Mr. Mocatta by representative recipients of his charity. The address contains the signatures of 8000 persons, and upwards of twenty-five London hospitals were associated with the movement as well as seventy other non-Jewish institutions. Evidence of the esteem and regard in which Mr. Mocatta is held as a munificent supporter of various charities comes from all parts of the world. Thus signatures have been received from warm supporters of the movement from Paris, Berlin, Vienna, St. Petersburg, and most of the other important cities in Europe, while names have also been subscribed from Canada, America, Bombay, Cape Town, the United States, Jerusalem, and even from Australia. The album, which measures twenty-two inches by fifteen inches, and about four inches in thickness, is bound in pale blue levant morocco. Embedded in a framework of rich leather is a silver plaque designed by Mr. Solomon, a beautiful and artistic group representing Charity. The printing of the address itself has been worked on a rich dark red morocco leather with the letters impressed in gold. To Messrs. Zaehnsdorf, of Shaftesbury-avenue, is due the credit of producing so admirable and artistic a volume, which is a worthy symbol of tribute to the respect and affection in which Mr. Mocatta is universally held for the philanthropic services he has rendered to the world at large.

MEDICAL MAGISTRATE. — Mr. Robert George Reid, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., of Nagambie, Victoria, Australia, has been appointed a Justice of the Peace for the Central Bailiwick, Victoria.

THE GREAT WESTERN RAILWAY MEDICAL FUND SOCIETY.—The fiftieth annual meeting of this society was held at New Swindon on Jan. 19th. The report showed that there were 10,925 members. Eighty-three cases had been treated in the hospital during the year, the average daily cost of each hospital patient being 1*s.* 8*d.* The total income was £9064, including members' contributions of £7657. The chief items of expenditure were—medical officers, £5552; donations to hospitals, £187; management expenses, £381; the balance left being £820.

THE AFTER-CARE ASSOCIATION.—The annual meeting of this association will be held on Monday next, Feb. 8th, at 3 P.M., at 5, Hyde-park-square, W., by permission of Mr. and Mrs. Bonham Carter. This is the only charity in the United Kingdom having for its object the care of poor persons discharged upon recovery from asylums for the insane, and as such is worthy of all support from the profession. Persons subscribing not less than 5*s.* per annum or giving a donation of not less than £2 10*s.* become members of the association, but much larger subscriptions are needed. All communications should be made to Mr. H. Thornhill Roxby, at the Church House, Dean's Yard, Westminster, S.W.

WEST CORNWALL INFIRMARY. — The annual meeting of subscribers was held at the West Cornwall Dispensary and Infirmary, Penzance, on Jan. 20th, Prebendary Hedgeland, the President, being in the chair. The report showed that there had been 148 in-patients during last year, against 140 during the year before last. Simultaneously with the increase in the patients there was a diminution in the income, the subscriptions having fallen off by more than £18, the consequence being that the committee did not feel themselves in a position to purchase many things which were really wanted. The Edward Bolitho Convalescent Home had accommodated 68 patients, 42 of whom were sent from the infirmary. The contributions included gifts of £30 from the late Mr. W. Bolitho of Polwithen, of £500 from Mrs. W. K. Foster, and of £200 from Miss N. Bolitho, "In Memoriam, William Bolitho." The total expenditure for the year was £843, and the total receipts were £770.

ANOTHER UNREGISTERED DENTIST.—At the Hove Bench on Monday the magistrates heard a charge under the Dentists Act against James Galloway of 6, Goldstone-villas, who denied having used the descriptions of "dentist" and "surgeon dentist" as implying that he was specially qualified to practise dentistry. The chief evidence, as in the cases heard at Brighton recently, was supplied by private detectives, one of whom said that he asked Galloway if he was a qualified dentist, to which he replied that he was, and arranged to do certain work for £2. Another witness said defendant gave him a circular on which were the words "Dentistry at moderate charge. D.D.S., U.S.A., surgeon dentist." The defence was that Galloway had received the diploma of the Dental College at Kansas and that under one section of the Act he could practise if he could show that he was not an ordinary resident of the United Kingdom and that he held a qualification to practise in a British possession or foreign country and did not represent himself as being on the Register. As soon as he could make arrangements, he said, he was going back to the States. Defendant was, however, fined £2 and costs, including advocate's fee.

DIPHTHERIA IN LONDON.—The registered deaths from diphtheria in London in the week ended Jan. 23rd were 63 in number and were no fewer than 30 above the corrected decennial average for the third week of the period 1887 96. The numbers registered in the preceding three weeks had been 49, 71, and 52 respectively. Islington was credited with 8 of the 63 deaths, Camberwell with 6, Lambeth with 5, Hackney, Bethnal Green, and Battersea each with 4, and Hampstead, Poplar, and Bermondsey each with 3 deaths. Of the 63 deaths, 3 were of infants under one year of age, 37 in the succeeding four years, 19 in the next fifteen years, and 4 in persons aged over twenty years. The admissions to hospital during the week were 93, against 115, 104, and

Hosted by Google

108 in the preceding three weeks, and 881 patients remained under treatment in hospital on Saturday, Jan. 23rd. In the outer ring there were 10 deaths registered, of which 3 were in the Edmonton, 3 in the West Ham, 2 in the Brentford, and 1 each in the Carshalton and the Hayes districts. Last week the registered deaths from the disease in London fell to 53, but even so they were 17 in excess of the corrected decennial average for the fourth week. Hammersmith, St. Pancras, Islington, and Camberwell were each of them credited with 4 deaths, and Mile End Old Town, Lambeth, and Battersea sanitary areas each with 3 deaths. All the deaths were in young persons aged under twenty years, and 33 of them in the first five years of life. The deaths registered in the outer ring, however, showed an increase, being 21 in number, and were scattered widely round London—namely, in Kingston, Bromley (2), Isleworth (3), Brentford, Harrow, Willesden, Hornsey, Tottenham (2), Edmonton, and in the West Ham registration district (8).

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Destitution in London.

A RETURN is being prepared of the number of deaths in the administrative county of London in the year 1896 upon which a coroner's jury has returned a verdict of death from starvation or death accelerated by privation, together with any observations furnished to the Local Government Board by boards of guardians with reference to these cases.

Half Holidays for Shop Assistants.

A Bill, backed by several private Members, has been introduced into the House of Commons which provides that every shop assistant shall have a half holiday in each week.

HOUSE OF COMMONS.

THURSDAY, JAN. 28TH.

Payments by Guardians to an Unqualified Person in Ireland.

In reply to Mr. J. P. Farrell the Chief Secretary to the Lord Lieutenant of Ireland replied that the Local Government Board had issued a writ against the Newry board of guardians, specially naming four members for the recovery of a sum of money paid by the guardians to Philip McGovern in direct contravention of the law. In October, 1895, the guardians passed regulations that these men and any other persons bitten by a mad dog who might thereafter apply were to be sent for treatment to McGovern, who claimed to be able to cure hydrophobia. The Board pointed out to the guardians that McGovern's farmhouse not being a recognised hospital within the meaning of the Act the guardians were acting *ultra vires* in sending patients to him for treatment. Upon the presentation of McGovern's bill the guardians applied to the Board to sanction the expenditure, which the Board explained they had no power to do, and as the account was not paid McGovern served the guardians with a civil bill for the amount. The guardians decided not to defend the process and judgment went against them accordingly by default. The Attorney-General had granted his fiat for the proceedings, which were now being taken in the superior court.

FRIDAY, JAN. 29TH.

Venereal Disease amongst the Army at Home.

Mr. Brodrick, Under Secretary of State for War, stated, in reply to a question on this subject put by Major Rasch, that on Jan. 1st the men under treatment for venereal disease at the several stations were 155 at Aldershot, 77 at Portsmouth, 84 at Woolwich, and 169 in Ireland. These figures gave the following rates respectively per 1000 of the strength:—12·13, 18·06, 16·79, and 8·93, with an average of 11·84.—Major Rasch asked whether the Government intended doing anything to remedy this state of things.—Mr. Brodrick replied to this that the whole question as related to India was under inquiry by a departmental committee of the India Office and no decision with regard to any steps could be taken until the results of that inquiry were obtained.

Petroleum Lamp Accidents.

Replying to a question by Captain Donelan relating to cheap oil and lamp accidents the Home Secretary said that it was among the questions which the Select Committee on Petroleum was considering. That Committee, he hoped, would be re-appointed shortly and would conclude their labours at an early date.

Army Medical Staff Examinations.

Sir Walter Foster asked the Under-Secretary of State for War whether the rule which prevents candidates for the Army Medical Staff who have twice failed in the competitive examinations again presenting themselves for examination has been or is to be set aside, and, if so, how many trials a candidate is to be allowed.—Mr. Brodrick: In future, on the recommendations of the medical authorities, three trials will be allowed.

MONDAY, FEB. 1ST.

The Payment of Vaccination Officers.

Mr. Holland asked the President of the Local Government Board whether, in view of the fact that vaccination officers were paid only by fees upon successful cases of vaccination and that therefore their incomes had been largely reduced in a great number of districts by the non-enforcement of the Vaccination Acts by boards of guardians while their actual work was in no degree diminished thereby, the Local Government Board would sanction boards of guardians paying the vaccination officers by fees based upon birth returns as well as upon successful cases of vaccination.—Mr. Chaplin replied that experience had amply shown the importance of payment of vaccination officers by results as a principle of general application, but he would consider whether any modification in the existing rule could be made under which the payment of the vaccination officer should not wholly depend on fees in respect of the certificates of successful vaccination registered.

Rabies.

Mr. Walter Long, President of the Board of Agriculture, replying to a question on this subject addressed to him by Dr. Farquharson, said that twelve cases of rabies had been reported in the county of London and twenty-two in the five home counties during the last six months. He was informed that the Public Control Committee of the London County Council proposed that present muzzling regulations should now be so far relaxed as to give exemptions to dogs under proper control and wearing a collar with the name and address of the owner. In this connexion he might perhaps be allowed to point out, however, that it would be necessary for the whole subject to be further considered in the light of the report of the committee which had been sitting for some time past to inquire into the working of the laws relating to dogs. He understood that the committee proposed that a determined effort should now be made to rid the country of rabies once and for all. If this could be accomplished, the necessity for the issue of intermittent muzzling regulations by particular local authorities would disappear. He was under the impression that the owners of dogs and the public generally would support a well-considered scheme which promised to secure the complete extirpation of rabies in these islands—a result which was never likely to be secured under the existing system.

TUESDAY, FEB. 2ND.

The Poor-law Officers Superannuation Act.

Mr. Chaplin, replying to a question put by Sir Walter Foster, said that the Local Government Board were of opinion that neither under the Superannuation Act of 1864 nor under the Act of last session, was a public vaccinator who was paid by fees under a contract, an officer to whom a superannuation could be granted. He was not contemplating any alteration of the law in this respect.

Scurvy among Indian Troops.

Lord George Hamilton said, in reply to a question, that the Indian troops at Suakin were attacked for a short time by a sudden outbreak of scurvy, during which 2 British officers, 103 men, and 85 followers were admitted to hospital suffering from this complaint. In about a month—viz., by the beginning of November—it was completely eradicated.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*
